Duccio married Ana Mori Tomatis from Lima though of Italian descent on June 15, 1962. They had two children, Bruna and Aurelio. Both children went on to earn their Ph.D., Bruna in biology and Aurelio in microbiology. Anita was the great love of Duccio's life, both at home and in their travels together. Duccio dedicated several of his publications to Anita.

After the death of his wife in 2004, Duccio was practically alone in Lima. He decided to move to Saskatchewan in Canada to be with his daughter, Bruna, and her husband, Thomas Fisher, and their sons, Lucas and Stephen. Duccio's son, Aurelio, lives in Seattle. Duccio left Lima in the spring of 2010 and lived in Canada for a year. Duccio died at the age of 77 on Saturday, August 4, 2012, in Magdalena de Cao, Ascope in Peru. He died during the last phase of his fieldwork at Huaca Prieta, Magdalena de Cao on the north coast of Peru.

Duccio and Tom Dillehay were codirectors of the research project.

Just a few days before Duccio left for his last trip to Peru, he finished editing the English translation of his book on corn (Cambridge University Press). His research on the subject was kept in characteristically good order and is ready for another scholar to continue. In Peru, he donated his archaeology library to the University of Trujillo as well as his collection of plant and small animal samples, which were left to the archaeobiology lab at the university. The remainders of his things including his extensive library on Peruvian archaeology were sent to his most recent residence in Saskatchewan. It was Duccio's wish that after his passing, his library would be donated as well.

Major Accomplishments

Duccio's career in archaeology began when he studied under Dr. Raúl Porras Barrenechea, a professor of history at the University of San Marcos. His teachers at the university also included Jorge C. Muelle, an art historian; Luis E. Valcáreal, an Andean ethnohistorian; Ella Dunbar Temple, a specialist in colonial institutions; Mons. Pedro Villar Córdova and Edward P. Lanning, both archaeologists; and, lastly, José María Arguedas, an anthropologist with a great passion for indigenous cultures. For Duccio, archaeology was not only a scientific discipline but a great passion for the living cultures of the past.

While he was still a student, he participated in the *First Roundtable for Anthropological Sciences*, organized by the University of San Marcos in 1958, and, with Lumbreras and Caycho, presented his archaeological study of Aya Orjo (1958). The same year, at the Second National Congress of Peruvian History, Duccio presented another paper dedicated to the analysis of ceramics from Puerto Viejo, Chilca (1959).

Duccio obtained his Bachelor's degree in 1960 with a thesis called *On the Teatino Style*. A year later, he received his Doctor of Letters with his thesis *Six Occupation Sites from the Bottom of the Lurin River Valley*. Both of Duccio's theses were in the field of ethno-archaeology and were completed at the University of San Marcos in Lima.

Immediately after obtaining his academic degrees, Duccio embarked upon a number of archaeological explorations, including excavations in the Huarmey Valley on behalf of the Botanical Museum at Harvard University (1960). He explored the northern Peruvian valleys with Donald Thompson (1961) and organized the Italo-Peruvian expedition in northern Peru (1961). He explored the Casma Valley with Donald Collier in 1962, and from 1962 to 1963, he took over the Catastro project dedicated to the pre-Hispanic monuments in the Lima Valley. This last project was commissioned by the Metropolitan Deliberations Board and included participation from Ramiro Matos and Félix Caycho. The report was published in five volumes, which are currently in the archaeological monuments inventory in Lima. From the 1960s through today, more than 70 % of the registered archaeological sites in the Lima Metropolitan area were destroyed.

In 1965, Duccio traveled to Rome to represent the National Culture Commission of Peru and participated in postgraduate courses on new techniques in archaeological exploration, which was sponsored by the Lerici Foundation (1965). From 1967 to 1968, he obtained a scholarship from the French government to further his studies in the Quaternary Geology Laboratory at the University of Bordeaux in France under the guidance of Professor François Bordes.

Duccio was a consistent participant in conferences and academic events dedicated to Andean archaeology, such as the XXXVII International Congress of Americanists in 1966 (La Plata, Argentina), the XXXVII International Congress of Americanists in 1968 (Stuttgart, Germany), and the International Congress of Americanists in 1970 and the XLI International Congress of Americanists in 1974 (Mexico). He also participated in the International Symposium "Criticism and Perspectives of Andean Archaeology" organized by the National Institute of Culture of Peru, UNDP, and UNESCO (Paracas, 1980) as well as the World Archaeological Congress in Southampton, UK, in September of the same year. He was a speaker at the Symposium "Recent Advances in

the Understanding of Plant Domestication and Early Agriculture" in 1986. He also organized the international meeting on the "State of Peruvian Archaeology" with Ramiro Matos (Lima, 1988) and the Symposium on "French Research in Peru" with the French Embassy, IFEA, and ORSTOM (Lima, 1988).

Duccio Bonavia taught at several Peruvian and foreign universities such as the National University of San Cristóbal de Huamanga in Ayacucho (1963–1964), the University of San Marcos (1964–1970), and the Peruvian University of Science and Technology (1968). He was a professor in the Biology Department at the University Peruana Cayetano Heredia de Lima (1971–2005). He was also twice a professor at the Friedrich Wilhelms University in Bonn, Germany, and participated in a seminar on anthropology under Max Uhle (1981 and 1983–1984).

His academic merits earned him several positions such as Honorary Professor at the National University of Trujillo (1994), Extraordinary Investigative Professor at the Peruana Cayetano Heredia University (2002), Honorary Professor at Ricardo Palma University in Lima (2005), and Doctor Honoris Causa at the National University of Trujillo (2006). Duccio also spoke several languages including Italian, French, Spanish, Serbo-Croatian, and English, following in the footsteps of his mentor Dr. Jorge C. Spring (Jorge C Muelle). Dr. Spring and Duccio were good friends and hosted several visitors to the National Museum of Anthropology.

Duccio was a member of the Society for American Archaeology, the Société des Americanistes de Paris, Société des Americanistes (Switzerland), Société Préhistorique Française, and the Institute of Andean Studies. He was an honorary member of the Permanent Council of the International Union for Prehistoric and Protohistoric Sciences (USA). He also served as a representative of Peru at the Peruvian Historical Society and the National Academy of History. He was also a corresponding member of the Royal Academy of Spanish History and the National Academy of Argentinian History and a member of the Sciences Academy of Latin America and a life member of the College of Peruvian Archaeologists and also of the Società Dalmata di Storia Patria.

Duccio traveled extensively throughout Peru, mainly in the coastal valleys as well as several places in the sierra and the jungle. With a team from the Biophysics Laboratory from the University Peruana Cayetano Heredia, he climbed the Pariacaca Mountain in 1985 to study the Inka sanctuary of the same name.

Among his major studies in the field of archaeology was a study of a Mochica mural painting in the Valley of Nepeña (1958), an exploration of the north coast with Ernesto Tabío and Donald Thompson (1959), a stratigraphic excavation at Ancon (1960), and an excavation at Huarmey commissioned by the Harvard Botanical Museum (1960). He organized the scientific expedition to the jungles of Ayacucho sponsored by the National University of San Cristóbal de Huamanga (1963). He also organized the excavations at the ruins of Yaro (Pajaten, 1966) and in the Chancay River basin (Lambayeque) under the auspices of the Royal Ontario Museum (1971), among others.

Duccio has contributed to the creation and the strengthening of several institutions devoted to Peruvian archaeology. He was the Chief of Investigations at the Archaeological Museum at the University of San Marcos (1956–1961). He was the head of the technical team of the Metropolitan Deliberations Board in their studies of historic and archaeological sites (1963), head of the Explorations Department of the National Museum of Anthropology and Archaeology in Lima (1964), then assistant director (1968–1979), and an archaeologist affiliated with the National Archaeological Board in Lima (1963). He was a member of the Committee of Monuments as part of the Peruvian Commission of UNESCO (1967), a consultant to the Ford Lima Foundation (1975–1980), founder of the Laboratory of Prehistory in the Department of Biology at the University Peruana Cayetano Heredia (1978), a member of the Commission for the technical rating of archaeological projects at the National Institute of Culture (1979–1985), and a founding member

and director of the Peruvian Association for the promotion of the social sciences (FOMCIENCIAS 1980).

Duccio received several fellowships throughout his life, including one from the Harvard Botanical Museum for his excavations in Huarmey (1960) and from the Ministry of Foreign Affairs of France for his studies at the University of Bordeaux with professor François Bordes (1967–1968), from the Royal Ontario Museum (Canada), from the Ford Foundation to excavate in Huarmey (1974), from the John Simon Guggenheim Memorial Foundation (New York, USA), and from the Harvard Botanical Museum (1976–1977), to investigate preceramic corn in Huarmey. He also received fellowships from CONCYTEC to draw a map of mural paintings in Peru (1983) and from the Ford Foundation to analyze the conditions of university teaching in archaeology in Peru along with Ramiro Matos (1989–1990). Their report was subsequently published.

He received funding from the French Institute of Andean Studies in 1993 to write a book on Andean camelids and to translate into English the Fish and Wildlife Service (1999). To write his last book on corn, he received funding from the University San Martín de Porres (2006).

Duccio's academic bibliography is incredibly varied and comparable to the classics in American anthropology. He dabbled in art, pre-Colombian urbanism, botany, zoology, ecology, paleopathology, the indigenous diet, parasitology, physiology of height, and some aspects of medicine. The following bibliography includes 14 books, seven monographs, 44 inserts as chapter books, 139 specialized articles in magazines, 39 articles, and 20 reviews and comments devoted to the publications of his colleagues. He has been a big supporter of the theory of the second center of domestication of corn in the Andes.

Bone Chemistry and Ancient Diet

Robert H. Tykot
Department of Anthropology, University of South Florida, Tampa, FL, USA

Introduction

Dietary practices are a fundamental aspect of human life, from the basic caloric necessities to the socioeconomic variables which affect food production, acquisition, preparation, and consumption and how that may vary seasonally as well as over an individual's lifetime. Archaeologists have used many different data sources to study ancient dietary practices, including direct evidence from animal bones, macrobotanical plant remains, pollen and phytoliths in the soil, organic residues in pottery, and coprolites, as well as indirect evidence from skeletal pathology,

dental wear patterns, ethnographic observations, writings, and artistic depictions. Nevertheless, for most such studies, the results are just the determination of the main menu, with animal foods the only source of semiquantitative dietary estimates.

It was only in the late 1970s that a new area of research developed – bone chemistry – which has expanded considerably our understanding of human dietary practices (Vogel and van der Merwe 1977). Biochemically, you are what you eat, and bones, teeth, and other tissues preserved in the archaeological record may be analyzed and provide direct information about the diet of individuals. This has led to research on how diets may vary based on age, sex, and socioeconomic status, as well as between different sites and time periods (here are some of the recent synthetic publications about stable isotope analyses and human diet: Tykot 2004, 2010; Pollard and Heron 2008; Lee-Thorp 2008; Price and Burton 2011; Makarewicz and Sealy 2015).

Specifically, the combination of stable carbon and nitrogen isotopes in bone collagen and other tissues, and carbon and oxygen isotopes in bone apatite or tooth enamel, may be used to reconstruct prehistoric diet because of differential isotope fractionation between certain plant groups of atmospheric carbon dioxide during photosynthesis and trophic level increases in nitrogen isotopes. This allows us to distinguish between plants that follow different photosynthetic pathways; those which are nitrogen fixing versus absorption; and consumption of foods from different trophic levels, especially aquatic fish and mammals versus terrestrial plants and animals, but also between hunter-gatherers and agriculturalists, and even address short-term dietary change through microsampling of tooth roots and hair. Trace elements such as barium and strontium provide additional information about food sources and diet, while oxygen isotope analysis is used to study potential seasonality of shellfish gathering, and along with strontium and lead isotope analysis the mobility of the consumers.

Reliable isotope results have been obtained from samples of our early human ancestors, while the use of modern instruments which require only tiny samples and have a low per-sample cost has led to hundreds of archaeological bone chemistry studies around the world, with frequent publications in the *Journal of Archaeological Science*, the *American Journal of Physical Anthropology*, *Archaeological and Anthropological Sciences*, and the *International Journal of Osteoarchaeology*.

Key Issues

Principles of Stable Isotope Analysis

There are two stable isotopes each for carbon (^{12}C, ^{13}C) and nitrogen (^{14}N, ^{15}N), and three for oxygen (^{16}O, ^{17}O, ^{18}O) (Fig. 1). The lightest isotopes for each are the most abundant in nature (c. 99% for each), while the small but measurable amount of variation in the heavier isotopes is measured in parts per thousand or per mil (‰). High-precision stable isotope measurements using stable isotope ratio mass spectrometers are reported using the delta notation ($\delta^{13}C$, $\delta^{15}N$, $\delta^{18}O$) relative to internationally recognized standards:

For carbon and oxygen, the standard is *Belemnitella americana* from the Pee Dee limestone formation in South Carolina, while for nitrogen, it is AIR.

While all terrestrial plants photosynthesize CO_2 from the atmosphere and turn it into complex carbon-based molecules, there are three different photosynthetic pathways for plants which result in differences in their carbon isotope ratios which are then passed on to their consumers (Fig. 2). Trees,

Bone Chemistry and Ancient Diet, Fig. 1 Stable isotopes with different numbers of neutrons in the nucleus

Bone Chemistry and Ancient Diet,
Fig. 2 General pattern of photosynthesis showing carbon isotope fractionation

shrubs, and grasses from temperate regions follow the C_3 (Calvin-Benson) pathway and have $\delta^{13}C$ values averaging about −26.5‰, while grasses native to hot, arid environments follow the C_4 (Hatch-Slack) pathway and have $\delta^{13}C$ values averaging about −12.5‰ (although maize is more positive, c. −10‰). There are also some differences between particular species of plants and for the same plant grown at different latitudes (Fig. 3). Succulent plants like cactus utilize the CAM (crassulacean acid metabolism) photosynthetic pathway, with carbon isotope ratios often similar to those of C_4 plants but much more variable due to local ecological settings. In heavily forested areas, a canopy effect occurs due to incomplete atmospheric mixing and results in even more negative carbon isotope ratios. Atmospheric carbon isotope ratios have become depleted by about 1.5‰ since the industrial revolution, so values obtained on modern terrestrial plants and animals must be adjusted accordingly for comparison with most archaeological studies.

Wheat, barley, and rice are the most widely used domesticated C_3 cereal crops, while maize (corn), millet, and sorghum are the main C_4 domesticates. Stable carbon isotope analysis therefore has been widely used to address the importance of maize in the Americas and millet in Europe, Africa, and Asia.

For isotopic analysis of human remains to study diet, different tissues may be tested. Bone is made of a complex organic material called collagen (mostly a combination of essential and nonessential amino acids) and the bone mineral known as apatite (calcium hydroxyphosphate carbonate). Tooth enamel has a similar structure to bone apatite, while tooth roots have both collagen and apatite. Hair is made of keratin, a proteinaceous compound like collagen.

Empirical carbon isotope data for large mammals, along with data for laboratory-raised rats and mice, indicate that bone collagen $\delta^{13}C$ is metabolically enriched about +5‰ relative to diet, although this value is affected by the proportion of protein in the total diet and any differences in $\delta^{13}C$ values between protein and energy sources. Studies have shown that bone collagen is disproportionately produced from the protein portion of the diet, while bone apatite and tooth enamel are produced from a mixture of dietary protein, carbohydrates, and fats (lipids). Experimental data on rats show that bone apatite is enriched about +9.5‰ relative to the whole diet, regardless of the variety or isotopic composition

Bone Chemistry and Ancient Diet, Fig. 3 Carbon isotope ratios for modern C_3 and C_4 plants

of the foods consumed (Ambrose and Norr 1993; Tieszen and Fagre 1993), while data for larger herbivores and humans suggest that the diet-apatite spacing is about +12‰ (Tykot et al. 2009). Stable carbon isotope analysis of both bone collagen and apatite thus permits quantitative estimates of several dietary patterns.

Carbon isotope ratios for freshwater and marine foods are more variable than terrestrial plants and animals, due to differences in carbonate values in the water and trophic status, with marine (saltwater) fish having positive $\delta^{13}C$ values similar to that of maize. Fish and sea mammals, however, typically have much higher nitrogen isotope values, and their high protein content contributes much more carbon to bone collagen than does maize (c. 10% protein) or other plants. In contrast, carbon isotope ratios for bone apatite, which equally represent dietary carbohydrates, fats, and proteins, allow for the identification of just a few percent of C_4 plants in an otherwise C_3-based diet.

Nitrogen isotope ratios for plants depend primarily on whether they obtain their nitrogen by symbiotic bacterial fixation or directly from soil nitrates but also vary according to rainfall, altitude, and other factors. Plant values also may be elevated due to human-led fertilization practices. From their local baseline values, nitrogen isotope ratios increase about 3‰ for each trophic level due to metabolism, with lots of variation among marine organisms. Humans dependent on terrestrial plants and animals usually have $\delta^{15}N$ values in bone collagen of about 6–10‰, whereas consumers of freshwater or marine fish and sea mammals may have $\delta^{15}N$ values of 15–20‰. The most accurate interpretations may be made when there are isotopic data available for the animal and plant foods likely to have been consumed by a specific population, so testing is often

Bone Chemistry and Ancient Diet, Fig. 4 Carbon versus nitrogen isotope ratios for a typical food web. Isotope ranges may vary by region

done not just on human remains but also faunal and floral samples found at archaeological sites (Fig. 4).

Oxygen isotope analyses are also used to study ancient diet. Oxygen isotope values relate directly to local climate, temperature, and humidity and are used for determining the seasonality of shellfish, climate studies, mobility, and their impacts on dietary patterns. Analyses have been done on oxygen in both the carbonate and phosphate components of bone apatite and tooth enamel. Strontium isotope ratios directly represent the geographic area of food production/acquisition and thus the mobility of dietary resources and/or their consumers. Strontium isotope analysis has been used for migration studies in many parts of the world (see Meiggs and Freiwald's entry "▶ Human Migration: Bioarchaeological Approaches," in this encyclopedia).

Adult human bone collagen and bone apatite have resorption/replenishment rates estimated at 7–15 years or more, depending on the particular bone, so that isotopic analysis of bones of adults provides the average diet for many years prior to death. Tooth tissues, however, do not turn over, so their isotope values represent diet from the time of formation, regardless of age at death. Tooth formation begins in utero for deciduous teeth and ranges from 0 to 18+ years of age for permanent teeth. The analysis of multiple teeth from the same adult individual may reveal the age of weaning (first the introduction of solid foods and later the cessation of breast feeding) since a nursing infant is effectively a carnivore and will have much higher $\delta^{15}N$. Differences between juvenile teeth and adult bone values may reflect changes in diet due to geographic movement (e.g., for marital reasons) or change in status.

Stable isotope analysis of multiple human tissues can provide a science-based dietary life history of an individual. Although collagen is rarely preserved in bones predating the Upper Paleolithic and even for recent time periods is often badly degraded in hot and moist environments, bone apatite has provided reliable results throughout the Holocene and tooth enamel for early hominins back into the Miocene. Microanalysis of tooth segments (or hair or fingernails, when preserved) may be done to address short-term isotopic dietary variability, perhaps due to seasonal mobility or harvesting practices.

Sample Preparation and Stable Isotope Analysis

For isotope analysis of archaeological bone, the first step is to remove any potential contamination, either from the soil or from added preservatives, for a sample weighing about 1 g. It is then

necessary to separate the specific tissues to be analyzed. For collagen, this involves demineralization of the bone using acid and separation from any residual lipids. The procedures used in the Laboratory for Archaeological Science at the University of South Florida involve demineralization in 2% hydrochloric acid (72 h), removal of base-soluble contaminants using 0.1 M sodium hydroxide (24 h before and after demineralization), and dissolution of residual lipids in a 2:1:0.8 mixture of methanol, chloroform, and deionized water (24 h) (Fig. 5).

Bone collagen is often not well preserved, and a yield of less than 1% is considered unreliable for isotope analysis (bone originally has more than 20% collagen). The main issue for low yields is that degradation may have resulted in unequal breakdown and loss of the different amino acids, which individually have different isotope values because of the different chemical reactions involved in their initial production. The amount of carbon and nitrogen measured by the mass spectrometer, relative to the size of the sample put in for analysis, and the C to N ratio of the gases produced (which should be the same as in living organisms) are additional tests of reliability. Duplicate 1 mg samples of collagen pseudomorphs are placed in tin capsules and analyzed for $\delta^{13}C$ and $\delta^{15}N$ in continuous flow mode using a Carlo-Erba NA2500-II EA with a Costech Zero-Bank autosampler, coupled with a Thermo Delta + XL stable isotope ratio mass spectrometer in the Paleolab at USF (Fig. 6a).

Bone Chemistry and Ancient Diet, Fig. 5 Chemical extraction of bone collagen for isotope analysis

Bone apatite and tooth enamel carbonate are prepared using procedures designed to remove nonbiogenic carbon without altering the biogenic carbon isotope values (see Tykot 2004). About 10 mg of powdered sample is immersed in 2% sodium hypochlorite to dissolve organic components (24 h for enamel, 72 h for bone apatite), followed by the removal of nonbiogenic carbonates using 1.0 M buffered acetic acid for 24 h. The integrity of apatite and enamel samples is assessed through yields obtained in each stage of the pretreatment process and the CO_2 yield during the mass spectrometry analysis. More complex tests of sample reliability have been used in some laboratories, however, including Fourier transform

Bone Chemistry and Ancient Diet, Fig. 6 Stable isotope mass spectrometers in the Paleolab at the University of South Florida connected (**a**) to a CHN analyzer for collagen and other organic samples; (**b**) to a gas bench for bone apatite, enamel, and other carbonate materials

infrared spectroscopy (FTIR). Apatite and enamel samples weighing 1 mg are isotopically analyzed on a ThermoFisher MAT253 IRMS coupled to a GasBench-II + continuous-flow interface (Fig. 6b). It is a scientifically sound idea to perform repeat isotope analyses for outliers when testing a group of individuals thought to have had similar isotope values.

For both bone collagen and apatite/enamel carbonate analysis, reference gases and solid standard samples are analyzed to ensure reliability of the isotope results. The analytical precision for stable isotope ratio mass spectrometers is typically 0.1‰ or less for ^{13}C and ^{18}O and 0.2‰ for ^{15}N.

Estimating the percentage of C_4 plants in human diet is fairly straightforward for herbivores and human agriculturalists, if seafood was not available and animals were not consuming wild C_4 grasses, by simple interpolation between the endpoints of bone apatite for a pure C_3-based diet versus a pure C_4-based diet. Rather than using the average endpoints of −26.5‰ and −12.5‰, the specific carbon isotope values for the C_3 plants most likely consumed should be used, since they do vary between grasses (e.g., wheat, barley, rice) and legumes, etc., in order to set an accurate baseline. For a C_4 endpoint based on maize, the value would be about −10‰. So if the range was from −24‰ to −10‰ (14‰), then each per mil more positive than −24‰ would represent about 7% maize in the overall diet.

When animal or aquatic foods are a significant part of the diet, the bone collagen carbon and nitrogen isotope data are necessary to include in the percentage calculations. Mathematical models have been developed to combine collagen and apatite isotope data for distinguishing between plant and animal food sources with similar isotopic signatures, more recently by using multivariate statistics (Froehle et al. 2012).

Trace Element Analysis

A number of studies have been done measuring and interpreting trace elements in bone mineral, including Sr, Ba, Fe, Cu, Mg, Mn, Zn, and Pb. Lead is a toxic element known to accumulate in bone due to the usage of lead-based drinking, cooking, and eating materials, as well as toy soldiers, paint chips, and other items children have ingested. Strontium and barium however are structural substitutes for calcium in bone apatite and tooth enamel and show significant trophic level variation in their concentrations. Both Sr and Ba are acquired by plants through the soil and are then passed on to their consumers, with a decrease in concentrations for each trophic level. This fractionation is even greater for Ba than Sr due to its chemical structure as barite ($BaSO_4$) in the soil. There is, however, considerable geological variability in the soils, so that archaeologists must be extremely careful in making interpretations about the relative importance of plants versus meat in the diet. Testing of herbivorous and carnivorous animals, and plant foods if available, from the same area is highly recommended. In addition, care is needed in taking samples from bone with minimal contamination or diagenesis (Burton and Price 2000). Most elemental analyses of bone have been done by ashing the sample, dissolution, and using an ICP spectrometer; some more recent studies where sample removal was not allowed have been done nondestructively using an X-ray fluorescence spectrometer (Fig. 7).

Trace element measurements of bone are reported relative to calcium, e.g., Sr/Ca and Ba/Ca, or logarithmically, e.g., log (Ba/Sr). Much greater differences in the Sr and Ba concentrations and in the Ba/Sr ratios have been observed for marine versus terrestrial diets.

Recent Applications

Stable isotope analysis of human remains to study ancient diets has expanded considerably in the past 20 years, with several dozen or more publications in each of the last few years. The main issues being addressed include:

Early hominin dietary practices
Seafood consumption by near-coastal populations
Dietary contribution of freshwater resources from lakes and rivers
Mesolithic-Neolithic dietary changes

Bone Chemistry and Ancient Diet, Fig. 7 Nondestructive trace element analysis of bone using a portable X-ray fluorescence spectrometer

Importance of millet in East Asia, Africa, and Europe
The spread of maize in the New World
Dietary differences based on sex and/or status
Weaning practices
Mobility and migration

Following is an overview of two areas of my own research, specifically the importance of maize and seafood in different areas of peninsular Florida and the dietary practices of coastal and island inhabitants in the Mediterranean.

Florida

Bone collagen and apatite for more than 100 human individuals from 7 sites in peninsular Florida were analyzed by stable isotope mass spectrometry to test for the presence and increasing importance of maize in the southeastern United States (Tykot et al. 2005; Kelly et al. 2006). Previous studies, mostly on bone collagen, had clearly indicated maize was a dietary staple for the Mississippian culture by about 1000 CE, but it had been thought that maize may never even have reached southern Florida. At the inland site of Melton Mound, however, positive carbon isotope ratios especially for bone apatite and tooth enamel fully support that C_4 plants such as maize were a small but noticeable part of the diet by 600–800 CE. Four sites near the Gulf Coast were tested, with individuals from Bayshore Homes (Safety Harbor period) and Dunwoody (Late Caloosahatchee) averaging much lower $\delta^{15}N$ in bone collagen and more positive $\delta^{13}C$ for bone apatite, relative to the earlier Bay Pines (Weeden Island I) and Pillsbury (Manasota) sites, while the $\delta^{13}C$ results for bone collagen were similar for all four (Fig. 8). This strongly supports that it was a plant such as maize (with much less protein than fish but having an equal impact on apatite $\delta^{13}C$ values) did become a dietary staple in this region by the early second millennium CE. For all sites, however, there was also a large range of variation among individuals, and at least at one site, it seems that males had higher nitrogen isotope values than females, perhaps due to greater fish consumption. This is being investigated further through elemental analysis of Ba and Sr, which in a separate study has shown a much greater importance of seafood at sites on the Gulf Coast when compared with those near Miami on the Atlantic side of Florida (Fig. 9).

The Mediterranean Region

In the Mediterranean world, while seafood is a regular part of many modern people's diet, there is little in the way of shell mounds or other archaeological evidence that it was a staple in ancient times, even prior to the Neolithic. However, for Mesolithic sites on the Atlantic coast, including Portugal and Spain, isotope studies have shown that seafood was a major part of the diet (e.g., Richards and Hedges 1999). In contrast, an early study using both stable isotope and elemental analysis on Mesolithic coastal sites of Arene Candide in Liguria and Grotta dell'Uzzo in Sicily

Bone Chemistry and Ancient Diet, Fig. 8 Stable isotope data for selected precontact archaeological sites in Florida. (**a**) $\delta^{15}N$ versus collagen $\delta^{13}C$; (**b**) $\delta^{15}N$ versus apatite $\delta^{13}C$

(Francalacci 1989; Mannino et al. 2011) suggested that seafood was not a staple in the Mediterranean, and beginning in the Neolithic when there were domesticated sheep, goat, cattle, pig, wheat, barley, and other crops, studies by many scholars have shown it was negligible at sites in Italy, Croatia, Greece, Tunisia, and even on the islands of Sardinia (Lai et al. 2007), Malta, the Balearics, and Crete. There are some modest isotopic differences in diet based on status in the Late Bronze Age, e.g., at Mycenae (Richards and Hedges 2008), while freshwater fish become important at some sites, but even in Roman times when there was regular, large-scale maritime seafaring, it appears there was little seafood consumption even at the port site of Isola Sacra near Rome (Prowse et al. 2004; Killgrove and Tykot 2013) (Fig. 10). It is important, however, to have isotope data for fish and shellfish in the specific region of study since there are cases where their isotope values are rather negative and thus overlapping with terrestrial plant and animal values. African millet, a C_4 plant, was apparently present in Europe in the Neolithic, but not isotopically noticeable until the Bronze Age in northern Italy (Tafuri et al. 2009) and Iron Age at sites in Greece and Slovenia (Murray and Schoeninger 1988).

Future Directions

The analytical methods and examples presented above for human bone and other tissues do not include all of the scientific ways to study ancient diets. Stable isotope analyses have been done on individual amino acids in bone collagen, on cholesterol preserved in bones and teeth, on dental calculus, on carbonates and humic matter in soils, and on organic residues (lipids) absorbed in pottery. Still being developed are other ways to study diet, including isotopic analyses of calcium, sulfur, and hydrogen, and decreasing even further the size sample necessary for analysis.

Bone Density Studies in Environmental Archaeology

Yin-Man Lam
Department of Anthropology, University of Victoria, Victoria, BC, Canada

Introduction

Archaeologists and paleontologists have long recognized that the ability of bones to survive in the fossil record varies as a function of their intrinsic physical characteristics. Of these characteristics, bone density has become the most commonly used proxy measure of the potential of a specific skeletal element to survive site formation processes. In the analysis of archaeological faunal assemblages, bone density data have provided a framework for the assessment of preservational bias. Density-mediated destruction of faunal remains may result in a *sample assemblage* that is not representative of the *deposited assemblage* (terminology after Klein and Cruz-Uribe 1984), and this bias may affect the interpretation of important lines of faunal evidence such as skeletal element abundance, age/mortality profiles, and species representation. Studies have documented a wide range of bone density across the various elements within a skeleton, demonstrating the importance of basing counts of elements (MNE) and individuals (MNI) in archaeological assemblages on skeletal portions of high density.

The primary challenges in bone density research have been the derivation of accurate density measurements and the establishment of methodological standards. Over the past three decades, density data sets have been published for numerous species of mammals, birds, and fish. However, researchers have employed different methods in measuring and calculating "bone density" values. As a result, published bone density data sets vary significantly in their accuracy and are typically not suitable for comparison with one another. Most studies have been based on very small samples; those that have involved large samples have documented significant intraspecific variation in bone density.

Definition

Bone is made up of an organic matrix, a mineral component, and water. The organic matrix is primarily collagen, with a small proportion of non-collagenous proteins. The mineral component consists almost exclusively of hydroxyapatite, a calcium phosphate (Martin et al. 1998). The (dry) mass of a bone divided by its volume is known as its *apparent density* or *structural density*. Lyman (1984) emphasized a further distinction between *true density* (mass divided by volume exclusive of pore space) and *bulk density* (mass divided by volume inclusive of pore space); "pore space" includes any medullary cavity. Many studies have employed techniques that measure exclusively the mineral component of bone samples, producing data on *bone mineral density*.

The "bone density" data sets published in archaeological literature differ in terms of which property ("true density" or "bulk density") they attempt to represent and how accurately these properties have been measured. This variability reflects the diversity of methodologies used by researchers and has resulted in a current state of uncertainty in which "bone density" may refer to a certain property in one study but a different property in another. Consequently, the bone density data set from any given study is typically

unsuitable for comparison with those from others. This observation may even apply to studies conducted by the same research group; in a number of cases, researchers have altered their methodology for calculating bone density over time, with the result that the data produced in their more recent studies are not appropriate for comparison with those of their earlier studies. In numerous cases, methodological shortcomings have resulted in published bone density data that are inaccurate and of limited use in archaeological analyses (Lam and Pearson 2005). The methodology for any study must be examined carefully in order to determine the actual property to which "bone density" refers.

Key Issues/Current Debates/Future Directions/Examples

Archaeological studies of bone density were first conducted by some of the pioneers of taphonomic research (Brain 1969; Behrensmeyer 1975; Binford and Bertram 1977), who were interested primarily in applying these data to interpretations of the Plio-Pleistocene archaeological record. Perhaps the most well-known application of bone density studies was that of Brain (1969), in his assessment of Dart's proposal of an osteodontokeratic culture among australopithecines. Brain observed that the faunal preservation at the early South African cave sites more likely reflected patterns of bone density than selection, use, and manufacture by early hominins.

These early studies of bone density used water displacement to measure a range of artiodactyl skeletal elements, but differences in methodology resulted in inconsistencies between the density data produced by each study. Subsequently, most studies of bone density have been conducted using photon densitometry, a technique introduced to zooarchaeological research by Lyman (1984). Photon densitometry provided the advantages of being nondestructive and able to measure elements at very specific locations – known as "scan sites" or "regions of interest" (ROIs). While the earlier water displacement studies had measured the density of entire elements (providing a single value for each element) or, in the case of long bones, proximal and distal halves, Lyman's use of scan sites took into account the heterogeneous composition of most skeletal elements by defining multiple points of measurements for each. The scan sites defined by Lyman have become accepted as standard locations of density measurement by subsequent researchers, with modifications made to account for morphological variations among different taxa.

Despite Lyman's attempt to provide standardized parameters for bone density studies, the adoption of photon densitometry ironically resulted in greater incompatibility among the bone density data sets produced in the past two decades. Photon densitometers measure bone mineral *content* across a scan site (Fig. 1). In order to transform this measure of bone mineral content into a (bone mineral) *density* value, researchers must independently determine the volume of the scan site – the cross-sectional area of the site multiplied by its thickness, which is typically set by the machine (e.g., 1 mm). Despite having in common their use of photon densitometry, Lyman and other researchers employed different methods to estimate this cross-sectional area, affecting the accuracy and comparability of their density data sets. The end result has been that the practical definition of "bone density" varies from study to study. In some studies, the cross-sectional areas of all scan sites have been assumed to be a rectangle or a circle. Other studies have devoted greater effort to produce more precise measurements of the shape of the bone cross section. However, photon densitometry cannot determine the volume or shape of internal cavities; at best, it can measure *bulk density*, but not *true density*. With a few exceptions, researchers who employed photon densitometry did not take the additional steps to exclude internal cavities in their calculations of "density"; the failure to account for such cavities results in artificially low density values at the scan sites where they occur.

In order to address this shortcoming of photon densitometry, computed tomography (CT) has been used to measure bone mineral density for several species of mammal (Lam et al. 1999).

Bone Density Studies in Environmental Archaeology, Fig. 1 A schematic representation of photon densitometry, after Kreutzer (1992). The detector cannot determine the shape of the bone; it measures bone mineral *content*. The accuracy of the density value derived for each scan site (in this illustration, the middle shaft portion of a long bone) directly reflects the accuracy of the determination of the cross-sectional area. In "A," the cross section of the scan site is estimated to be a *rectangle* of maximum width and height. Such data underestimate the density of all scan sites and are categorized here as Class A. In "B," the external outline of the cross section is measured, but the internal cavity is not. Data produced in this manner are categorized as Class C and represent *bulk density*. They underestimate *true density* wherever an internal cavity occurs. Data that account for both external and internal shape ("C") are categorized as Class D and represent *true density*. The assessment of internal shape must be conducted independently of photon densitometry

The use of CT enabled precise assessment of the cross-sectional shape, including that of internal cavities, of each scan site and resulted in the most accurate bone mineral density measurements to that point. CT analysis of several ungulate taxa documented the highest bone density to be, among cranial elements, in the teeth and the petrous and, among postcranial elements, in the middle shaft portions of long bones (Lam et al. 1999).

Despite the advantages of CT, the use of photon densitometry has remained common in bone density studies. Recently, another nondestructive technology – digital photodensitometry – has been introduced to archaeological research into bone density. This technology allows the examination of large samples at low cost but, like photon densitometry, cannot measure internal cavities (Symmons 2004). In order to produce accurate density measurements, these technologies must be supplemented with the use of an independent method, such as water displacement or CT, that can determine the size of internal cavities.

The problematic effects of multiple methodologies of variable accuracy and precision can be seen in the divergent density values that have been produced for a single taxon (Fig. 2). Lam and Pearson (2005) conducted a review of bone density studies in archaeology, categorizing published density data sets for mammalian taxa into one of four classes: A–D, from least accurate to most accurate. Class A studies calculated density as if the cross section of the bone was a rectangle, with sides of maximum width and height (Fig. 1a). This invariably represents an overestimation of the cross-sectional area, resulting in an underestimation of bone density. The degree of inaccuracy varies with scan site,

	I	II	III	IV	V
FE 1	0.28	0.34	0.57	1.03	0.60
FE 2	0.16	0.40	0.38	0.75	0.61
FE 3	0.20	0.39	0.46	0.76	0.66
FE 4	0.36	0.51	0.69	1.01	1.33
FE 5	0.24	0.41	0.54	0.81	0.56
FE 6	0.22	0.23	0.35	0.85	0.50

bone mineral density (g/ml)

Bone Density Studies in Environmental Archaeology, Fig. 2 Published bone density values for different scan sites of a sheep or goat femur, taken from five different studies. Columns I, II, and III represent Class A data; column IV represents Class C data (bulk density); column V represents Class D data (true density). (See Lam and Pearson (2005) for sources)

depending on how closely the cross section of that site corresponds to a rectangular shape.

Studies categorized as Class B and Class C accounted for the external shape of the cross section, with Class B studies using a rough, geometric estimate (e.g., circle, triangle, polygon) and Class C studies deriving an actual measurement of the external outline of the scan site; however, neither accounted for the presence and size of the medullary cavity. The accuracy of Class B data varies according to how closely the geometric estimate matches the shape of the cross section. Class C data should be accurate for scan sites that have no internal cavity (Fig. 1b). Only Class D data demonstrate accuracy across all scan sites, accounting for both the shape of the external contour and any internal cavities, but data sets in this class remain few. Some studies have derived density values in more than one class for comparative purposes. Class C density values have been found to be up to 1000% higher than Class A values and Class D values up to 120% higher than Class C values for the same scan site (Lam and Pearson 2004).

The publication date of a bone density study does not inform as to the accuracy of the data it presents. In the past decade, some studies have continued the publication of Class A data, while others have presented methodological advances such as the combination of photon densitometry (to measure bone mineral content) and CT (to determine cross-sectional area) in the same study (Novecosky and Popkin 2005).

Class D data have proven significant in documenting the large difference in density between the epiphyses and shafts of long bones, a difference obscured by the inclusion in Class A–C data of the marrow cavity in the density calculations (Fig. 2). This observation has illustrated the importance of incorporating shaft fragments into the quantification of long bone abundance. Such fragments are more likely to survive in the archaeological record than those of epiphyses. Quantification based primarily on epiphyses will underestimate the overall abundance of long bones for situations in which density-mediated destruction has occurred; in addition, it may result in a bias for metapodials, which have relatively dense epiphyses and represent low-utility elements, over high-utility long bones such as femora, whose epiphyses are less dense. At Paleolithic sites, the failure to count shaft fragments may lead to a biased overrepresentation of low-utility elements, potentially resulting in the erroneous interpretation that the assemblage was accumulated through scavenging behavior (Marean and Kim 1998).

Lyman's (1984) bone density data set for deer was used widely by researchers, even in cases in which the species of interest was not deer. In the past twenty years, efforts have been made to collect density data for other species – primarily mammals (including humans [Galloway et al. 1997]), but also several species of fish (e.g., Butler and Chatters 1994) and bird (e.g., Cruz and Elkin 2003). Some studies of mammal species have observed significant intertaxonomic differences in bone density patterns; however, it remains unclear the extent to which they reflect differences in research methodology rather than actual differences in density. Lam et al. (1999) derived bone mineral density values for a small sample of bovid, cervid, and equid species, finding that overall patterns of bone density were extremely consistent among the three groups. Other studies (e.g., Gutiérrez et al. 2010) have found, for individual scan sites, a high degree of variation in bone density

among individuals within the same taxon. While some of this variation may be attributable to differences in age, with the bones of juveniles being less dense than those of adults, the effects of other variables such as sex, diet, health, and activity levels on bone density require further investigation. A thorough documentation of the range of intrataxonomic variability is a prerequisite to any assessment of differences in bone density between species.

Additional challenges to be addressed include the use of bone density data in quantitative analyses. The standard use of correlation/regression analysis in many studies to examine the relationship between bone density and bone survivorship requires the condition that each individual identified in a faunal assemblage was originally represented by an entire skeleton. It also requires the condition that all the preserved remains of that skeleton were recovered and identified. As neither condition is likely to hold for most archaeological fauna assemblages, researchers must modify their quantitative analyses as appropriate (Lam and Pearson 2004; Novecosky and Popkin 2005). Continued research is required to produce accurate density values for larger samples, to assess the range of intrataxonomic and intertaxonomic variability in bone density, and to provide effective methods for incorporating bone density data into archaeological analyses.

Bone Differentiation (Human and Nonhuman) in Archaeological and Forensic Contexts

Dawn M. Mulhern
Department of Anthropology, Fort Lewis College, Durango, CO, USA

Introduction

Differentiating human and nonhuman bone has important applications in both archaeological and forensic contexts and can be particularly challenging when skeletal remains are fragmentary. Archaeologists often make initial determinations about whether skeletal remains are human or not in the field, although more detailed analyses often take place in the laboratory, particularly for bulk bone recovered during excavation. In cases where skeletal remains are found unexpectedly, one of the first questions in establishing whether the remains have forensic significance involves determining whether they are of human or nonhuman origin. Differentiating human and nonhuman bone can be achieved through a variety of methods, including gross, histological, and molecular analyses. More detailed reviews of these methods can be found in Hillier and Bell (2007), Mulhern (2016), and Mulhern and Ubelaker (2012).

Definition

Human bone is most likely to be confused with mammalian bone, particularly mammals that are about the same size. However, the human skeleton is adapted for bipedal locomotion, resulting in many easily distinguishable skeletal features throughout the skeleton, particularly related to the morphology of joints and muscle attachment sites. The human skull is also readily identifiable, with the combination of a very large brain case and flat face. In general, human bones show less pronounced muscle markings and flatter, less sculpted joint surfaces than nonhuman mammalian bones. For a photographic reference for distinguishing human and nonhuman mammalian bone, see France (2009).

A large cranial vault and thinner cranial bones distinguish the human skull from other mammals of comparable size. Also, the opening to the brainstem (foramen magnum) is located directly underneath the skull in humans and toward the back of the skull in quadrupedal animals. The human face shows no projection of the nasal area or the jaws, unlike other mammals.

In humans, the spine exhibits a characteristic "S" shape when fully articulated to accommodate upright posture. In addition, the size of the vertebrae becomes dramatically larger toward the lumbar spine because of the need to support body weight. In quadrupeds, the articulated spine has more of a "C" shape with vertebrae that are more uniform in size throughout the spine. Features found on some nonhuman vertebrae and not human vertebrae include interlocking accessory processes and an anterior ridge on the centrum.

The human thorax is most similar to an ape, with a broad, shallow rib cage resulting in ribs that have a more pronounced c-shaped curve than seen in a typical quadruped. Humans have a long clavicle and very mobile shoulder, elbow, and wrist joints. Also seen in apes, this combination of features is not characteristic of other mammals of similar size. Most mammals have greatly reduced or absent clavicles as well as more stable, restricted shoulder girdles and elbow and wrist joints. Specific skeletal features to look for in humans included a rounded humeral head, reduced olecranon process of the ulna, and broad contact between the capitulum of the humerus and the radial head.

The human pelvis is unique among mammals, with a bowl shape capable of supporting internal organs with an upright posture. The broad iliac

blades accommodate the repositioning of gluteal muscles needed to offset torque forces caused by supporting the body weight on alternating limbs during bipedal striding.

The lower limbs in humans show many adaptations to bipedal locomotion. The thighs are angled from hip to knee to position the limbs directly underneath the body. This can be seen in the medial angle of the femur. The hip, knee, and ankle joints in humans are robust to accommodate body weight. The human tarsals are also very robust compared to other mammals. Humans have five digits in the foot; the first (medial) digit is the most robust. Many mammals have a reduced number of digits. Due to similarities in size and overall morphology, bear paws are commonly mistaken for human feet (and hands) in North America, particularly when partially fleshed with the claws missing. Anatomical differences between a human foot and bear foot include the relative length of the digits; humans have longer medial digits and bears have longer lateral digits. Also, the tarsal bones of a bear are not as robust as their human counterparts and the metatarsal heads of bears each have two associated sesamoid bones, whereas only the first metatarsal head in humans exhibits sesamoids. Specific features of the lower limbs characteristic of humans include a femoral greater trochanter that is shorter than the femoral head, a lateral lip on the anterior aspect of the distal femur that helps to hold the patella in place, and a platform-like talus.

In addition to an opposable thumb, the articular ends of metacarpals, metatarsals, and phalanges are smooth and rounded in humans for enhanced flexibility and mobility, whereas these elements often exhibit ridges and grooves for stability in nonhuman bone.

In cases where it is not possible to confirm or exclude human origin based on gross analysis, histological methods may be useful (Mulhern and Ubelaker 2012). Histological analysis is necessarily destructive and requires specialized equipment and training. Preparation of histological specimens typically involves removing a cross section of a bone and grinding it down to a thin wafer that can be mounted on a microscope slide for viewing under a light microscope. The overall organization of histological structures, as well as the size and shape of structures, may provide important clues regarding the bone's origin.

Mammals that grow quickly in size such as cows, deer, and sheep typically have bone that exhibits a plexiform structure, with a rectangular organization (Fig. 1). This type of pattern is not found in human bone and, if observed, can be used to rule out bone of human origin (Mulhern and Ubelaker 2012). A pattern of linear bands of primary and/or secondary osteons is commonly found in nonhuman bone (Fig. 2). Three dimensional techniques for observing bone microstructure have recently revealed that osteon banding may also be found in human bone (Anndronowski et al. 2017). Human bone is usually characterized by haphazardly distributed secondary osteons, or

Bone Differentiation (Human and Nonhuman) in Archaeological and Forensic Contexts, Fig. 1 Plexiform bone in a sheep femur

Bone Differentiation (Human and Nonhuman) in Archaeological and Forensic Contexts, Fig. 2 Osteon banding in a miniature swine femur

Bone Differentiation (Human and Nonhuman) in Archaeological and Forensic Contexts, Fig. 3 Haversian bone in a human femur

Haversian systems embedded within lamellar bone (Fig. 3), but is not unique in this respect, as many other mammals (including those with plexiform bone) also have bone with this type of pattern. In particular, large carnivores exhibit Haversian bone like humans. This is potentially problematic in a forensic context, since size of the bones could be similar.

Key Issues/Current Debates

Attempts have been made to apply metric analysis of histological structures (such as osteon size or Haversian canal size) to identify differences among species, but the accuracy of many of these studies is questionable because they are based on small sample sizes (Mulhern and Ubelaker 2012).

Overall, studies show that humans have larger Haversian canals than most mammals, however most studies are based on relatively small sample sizes, so the extent of variability is not well understood. Osteon sizes in humans overlap those of other mammals, particularly those with medium or large body sizes. Several studies have also attempted to develop discriminant function equations that can be used for distinguishing human and nonhuman bone based on histomorphometrics. This new area of research involves an investigation of the circularity of osteons, which suggests that osteons in nonhuman bone are more circular than those found in human bone. A complete review of these methods can be found in Mulhern and Ubelaker (2012).

Biomolecular methods including radioimmunoassay and mitochondrial DNA analysis have also been used for species identification, which is particularly important in wildlife forensics; applications of these studies are summarized in Mulhern (2016). Collagen peptide mass fingerprinting has also emerged as a promising area for species identification, with published studies primarily in bioarchaeology (e.g., Buckley et al. 2009). The cost of such methods and access to specialized equipment makes gross analysis and histological methods preferable when possible.

Future Directions

Future directions for distinguishing human and nonhuman bone include an expansion of our understanding of the variability of bone histology among species as well as among and within bones of individuals, particullarly with nondestructive, three-dimensional imaging techniques. As more studies involving larger sample sizes provide additional data, the accuracy of methods used to distinguish human and nonhuman bone based on histological structures will likely improve. In addition, wider and cheaper access to biomolecular methods will allow for more accurate analysis of fragmentary remains.

Introduction

"Bone tool" is a generic term used to identify implements made of various animal tissues that include bone, tooth, antler, and ivory. During the Paleolithic (2.6 Ma to ~10,000 BP), these tools took different forms and have been studied by archaeologists to address a variety of questions. Researchers have investigated early purported bone tools in an attempt to identify firm criteria to distinguish between marginally modified or used tools and bones altered by natural causes. Bones interpreted as genuine tools have been investigated to gain a better understanding of early hominin adaptation, technology, and cultural traditions. Different research questions have concerned the emergence and diversification of formal bone tools, defined as functional artifacts shaped with techniques specifically conceived for bony tissue, such as scraping, grinding, grooving, and polishing. For much of the twentieth century, formal bone tools were seen as a technological innovation directly stemming from the spread of anatomically modern humans across Europe at the beginning of the Upper Paleolithic and strictly associated with a suite of critical inventions that followed this peopling event (cave and mobiliary art, personal ornaments, blade technology, complex funerary practices, musical instruments, etc.). Upper Paleolithic bone industries were used in this framework to support the scenario of a cognitive revolution occurring in Europe at c. 40,000 years ago. The discovery of bone awls and projectile points at a number of Still Bay (d'Errico and Henshilwood 2007) and Howiesons Poort (Backwell et al. 2008) sites from southern Africa, securely dated to between 75 and 60 ka, has challenged this view, but not the significance attributed by many archaeologists to this category of material culture. The early appearance of bone tools in the African Middle Stone Age, together with pigments and personal ornaments, has been used to support the so-called Out-of-Africa scenario for the origin of behavioral modernity, linking the origin of our species in Africa around 200,000 years ago with the gradual emergence of modern culture on that continent. In this context, bone tools are interpreted as a significant behavioral corollary of the emergence of anatomically modern humans in Africa. However, some authors have cautioned that Middle Stone Age sites with advanced bone tools are rare and that the cognitive implications of formal bone tool manufacture are uncertain (Backwell et al. 2008). In addition, bone industries that show a level of technological complexity, equivalent to

that normally associated with Upper Paleolithic cultures produced in Europe by modern humans, are associated with transitional technocomplexes such as the Châtelperronian in France and Spain and the Uluzzian in Italy and Greece. The former technocomplex is now firmly attributed to Neanderthals, but the authorship of the latter is uncertain due to the scarcity and ambivalent features of the human remains associated with those layers. This implies that the ability to produce formal bone tools may not be the preserve of modern humans. In parallel with these studies, the complexity of Upper Paleolithic bone tools has stimulated research seeking to document the technological, typological, and functional changes that characterized bone tool industries in Eurasia between 40 and 10 ka. In this review we will focus on these different topics and summarize recent advances in the field.

Definition

A bone tool is taken here to be an implement that can be used to achieve a task or modify or produce an item. This definition does not include categories of bone artifacts used in nonfunctional activities, such as musical instruments, notations, and ornaments. This entry focuses on Paleolithic bone tools from Africa and Europe.

Historical Background

Earlier Stone Age of Africa

Ever since Dart interpreted bones from Makapansgat as tools, an interpretation largely rejected, research interest has focused on whether some bone objects from early hominin sites should be interpreted as artifacts or the result of nonhuman taphonomic processes, which are known to produce pseudo-bone tools morphologically similar to human modified or used artifacts. Criteria for characterizing the patterns produced by specific agents are not always clearly defined, and the issue of equifinality compounds the problem. In light of this, it has become widely accepted that in order to distinguish between pseudo-tools and true tools, it is necessary to adopt an interdisciplinary approach, combining the analysis of a wide range of bones modified by known agents, taphonomic analysis of the fossil assemblages from which the purported bone tools derive, microscopic studies of possible traces of manufacture and use, experimental replication of the purported tools, and the quantification of the wear pattern. In 1959 Robinson proposed that a metapodial shaft fragment with a smoothed and pointed end from Sterkfontein Member 5 West (~1.7–1.4 Ma) was a tool. Thirty years later Brain described 68 similarly modified bones and horn cores from Members 1–3 at Swartkrans, dated ~1.8–1 Ma. Comparative scanning electron microscope inspection of replicas of the worn area on archaeological specimens, and experimental shaft fragments used to extract tubers from the ground and work skins, suggested to Brain and Shipman that the wear patterns on the smoothed tips of the Swartkrans specimens matched those produced experimentally. The anthropogenic nature of the material was later confirmed by Backwell and d'Errico (2001), based on comparison with a large reference collection comprising fauna modified by ten nonhuman agents, morphometric and fracture analysis of bone flakes from Swartkrans Member 1–3, experimental use of shaft fragments in a variety of tasks, microscopic analysis of natural, experimental, and archaeological wear patterns, and quantification of striation width and orientation on archaeological and experimental specimens. The breakage patterns and size of the bone tools, compared with the remainder of the faunal remains, indicated that early hominins selected heavily weathered, elongated and robust bone fragments for use as tools (Fig. 1). The wear pattern on the Swartkrans tools fitted most closely that created when excavating termite mounds in the Sterkfontein Valley. Evidence of shaping by means of grinding on some of the more robust horn cores suggests that the users had the cognitive ability to modify bone intentionally for optimal efficiency in the task for which they were used. These authors described 16 new bone tools from Swartkrans and used the enlarged collection to search for patterns of variation between members. No significant differences

Bone Tools, Paleolithic, Fig. 1 Selection of bone tools from the South African early hominin sites of Swartkrans (*top*) and Drimolen (*bottom*). (Images: Backwell & d'Errico)

were observed between Members 1–3 in the type and size of the bone fragments used as tools, as well as in the length and type of the wear pattern, demonstrating that no major changes occurred through time in the bone type favored and the motion in which the tools were used. A functional study of the Sterkfontein and Swartkrans bone tools was also conducted by Van Ryneveld, who experimentally used bone tools in a number of tasks and compared the resulting patterns with that present on the Swartkrans specimens using scanning electron microscopy. She concluded, based on visual comparison between wear patterns and the productivity of the various activities involved, an anthropogenic origin for the wear and that archaeological tools were used to excavate subterranean plant foods in dolomitic ground, debark softwood trees, process hides, and extract termites from their mounds. More recently, Backwell and d'Errico (2008) recognized 14 bone pieces from the nearby site of Drimolen as digging tools (Fig. 1), indicating that the use of these tools was widespread at sites in the Sterkfontein Valley. In an attempt to refine the functional interpretation of the bone tools from Swartkrans and Drimolen, they conducted a statistical analysis of 2D and 3D roughness variables obtained from a representative sample of archaeological, ethnographic, and experimental bone tools (d'Errico and Backwell 2009). Results show that the wear pattern on the early hominin bone tools from Drimolen is incompatible with that of tuber digging and very similar to termite foraging and fruit processing. Members

1–3 at Swartkrans contain the remains of the robust australopithecine *Paranthropus robustus*, while Members 1 and 2 have additionally yielded the remains of *Homo erectus*. The absence of this taxon in Member 3, from where most of the bone tools derive, suggests, but does not prove, that these implements were used by *Paranthropus robustus*. The association of a high number of *Paranthropus* remains with bone tools and the virtual absence of stone tools at Drimolen reinforces the hypothesis that *Paranthropus robustus* was the user of the South African bone tools. A different bone tool tradition is observed in East Africa, where Mary Leakey reported 125 artificially modified bones and teeth from Olduvai Beds I and II bearing evidence of intentional flaking, battering, and abrasion. These specimens derive from massive elephant, giraffe, and *Libytherium* limb bones, and to a lesser extent from equids and bovids, as well as from hippopotamus and suid canines. Shipman analyzed the collection microscopically and concluded that 41 of the bone pieces were modified by hominins and the remainder bore ambiguous traces, or evidence of abrasion by sediment. A patella, astragalus, femoral condyle, and magnum bearing puncture marks were interpreted as anvils, and 35 implements were described as bones shaped by flaking prior to use. Twenty-six were interpreted as light-duty implements used on soft substances (hide-working), and the remaining 11 described as heavy-duty tools utilized on mixed substances, perhaps in butchering or digging activities. Backwell and d'Errico (2004) reanalyzed the collection, focusing on fracture patterns and flake removals. Comparative microscopic analysis of different areas of the purported Olduvai tools, and of the edges of bone pieces from the rest of the faunal assemblage, suggested to these authors that the surfaces of all of the purported bone tools are affected by post-depositional abrasion, rendering impossible the interpretation of the function of the tools based on the wear pattern alone. However, analysis of breakage patterns and removals identified a reduced number of pieces that are likely candidates for having been intentionally knapped. These comprise fresh bone shaft fragments and epiphyseal pieces bearing five or more flake scars, some of which are contiguous, with one or more anomalously invasive primary removals (Fig. 2). Most of them reveal a particularly high proportion of bifacially arranged removals, and they are virtually unaffected by carnivore damage. They proposed that some bones functioned as handheld hammers (Fig. 2). An interesting aspect of their results lies in the stratigraphic occurrence of the bone tools. While Leakey and Shipman identified bone tools in all the beds, they identify, with one possible exception, bone tools only in Bed II. This suggests modification of bone fragments by knapping is not a behavior associated with the Oldowan, but with the more developed phases of this technological tradition (Developed Oldowan B) and/or the Early Acheulean. Knapped bone tools appear more systematically, according to their results, in coincidence with the appearance of remains of *Homo erectus* in middle and upper Bed II. The presence in a Bed II site of an intentionally knapped bone hand axe constitutes supplementary evidence that *Homo erectus* was responsible for the production of at least some of these bone tools. Similarly flaked bones are reported from other Acheulean sites, namely, Ternifine in Algeria, the Grotte des Ours in Morocco, and Gesher Benot Ya'aqov in Israel. Bones bearing traces interpreted as resulting from use are also reported at Melka-Konturé, Ethiopia, in layers dated to 1.7 Ma.

Lower Paleolithic of Europe

Intentionally flaked tools are reported from 12 Lower Paleolithic sites in Europe, eight of which are in Italy. Acheulean-type bifaces, made by flaking elephant long bones, are known from three Middle Pleistocene sites in Italy: Castel di Guido, Fontana Ranuccio, and Malagrotta (Costa 2010). The Castel di Guido and Fontana Ranuccio specimens, in particular, show multiple scars on both faces with clear negative bulbs of percussion (Fig. 3). The use of long bone shaft fragments and an equid phalanx used to retouch stone artifacts is documented at the Middle Pleistocene site of Boxgrove in England. Putative bone and ivory

Bone Tools, Paleolithic, Fig. 2 Selection of bone tools from Olduvai Gorge showing intentional shaping through knapping (*left*), and an elephant patella (*right*), with impact marks (details) resulting from repeated striking against a pointed stone. (Images: Backwell & d'Errico)

points have been reported from at least six Lower Paleolithic sites in Europe, namely, Mesvin in Belgium, Bilzingsleben in Germany, Lunel Viel in France, Castel di Guido in Italy, and Torralba and Ambrona in Spain. Shaped bone and ivory points from the sites of Torralba and Ambrona were thought to have been used as awls or with wooden hafts, with the use of hafted bone and ivory points implying the employment of a spear armature technology. However, a reappraisal of the ivory points from Torralba, Ambrona, and Castel di Guido concluded that these pieces are natural, resulting from the accidental breakage of the tusks during the life of the animal (Villa and d'Errico 2001).

Middle Paleolithic of Europe

The use of bone or antler bases to retouch stone artifacts is documented at many Mousterian sites from Europe including Combe Grenal, Artenac, and La Quina in France, Riparo di Fumane and Riparo Tagliente in Italy, and on the Crimean peninsula (Patou-Mathis 2002). Recently, a human skull fragment from the Mousterian site of La Quina has been shown to be the oldest evidence of a human bone used as a tool in the form of a retoucher (Verna and d'Errico 2011). Bone and antler points are reported from at least 12 Middle Paleolithic sites: Butesti and Budzujeni in Moldavia, Prolom II in Crimea, Salzgitter-Lebenstedt in Germany, the Broion cave in Italy,

Bone Tools, Paleolithic, Fig. 3 Lower Paleolithic bone hand axe made of *Elephas antiquus* limb bone from Castel di Guido, Italy. (Drawing: F. d'Errico)

Castillo in Spain, and several French sites such as Combe Grenal, Vaufrey, La Quina, la Grotte de l'Hermitage, Pech de l'Azé 1, and Camiac. Some of the pieces were interpreted as points hafted on throwing or thrusting spears, while others were described as awls and borers. A collection of mammoth ribs and fibulae from Salzgitter-Lebenstedt in Germany is said to have been intentionally pointed and/or flattened, but these objects require reappraisal before they can be accepted as genuine artifacts because similar objects have been shown to be the result of natural processes. Bone described as intentionally flaked or retouched has been reported from a number of Mousterian sites (e.g., Cueva Morin and La Quina), but the possibility that flaking may have resulted from fracture for marrow extraction by humans or carnivores has been excluded in only a few cases. Firm evidence of worked, and in some cases decorated, bone awls comes from Châtelperronian and Uluzzian sites in France and Italy (d'Errico et al. 2011). Findings at Arcy-sur-Cure and Quincay in France (Fig. 4), dated to between 40 and 38 ka BP, have yielded good evidence of complex bone technology in the form of shaped and decorated awls. The late Mousterian levels at Buran Kaya III in Crimea have yielded one bone haft made of a horse metapodial and several bone tubes made on wolf and hare long bones, dated to between 36 and 32 ka BP.

African Middle Stone Age

An increasing number of bone tools are reported from Middle Stone Age (MSA) sites in Africa. These include bone objects from Broken Hill (Kabwe), Zambia, attributed to the early MSA and thought to be associated with *Homo heidelbergensis* (elsewhere named *Homo rhodesiensis*) and interpreted as two gouges and a point. A point from Mumbwa Cave is considered doubtful. Other evidence for bone working in the MSA is provided by barbed and unbarbed bone points from the Katanda sites (Fig. 5) in the Semliki Valley, Democratic Republic of the Congo, dated ~90–60 ka (Yellen et al. 1995). A point tip, a mesial fragment, an almost complete spear point, a tanged bone point, and 26 awls are reported from M1 and M2 layers at Blombos Cave, with ages ~84–72 ka (Fig. 6). A single massive point, different from those found in the MSA and LSA layers at Blombos Cave, was recovered in the dune sand layer, with an age of ~70 ka (d'Errico and Henshilwood 2007). An awl and a possible flaked shaft fragment come from the Blombos M3 phase, with an age of 98.9 ± 4.5 ka. The morphological variability in the bone points from Blombos Cave, and the size and weight of the one complete specimen, suggests that they are more likely spear points than arrow points. The interpretation of the Blombos bone artifacts as spear points is consistent with ethnographic and recent archaeological stone point dimensions, which show spear tips to be five times larger than arrow heads. A bone point from Peers (Skildergatkop) Cave was retrieved from either the Howiesons Poort (HP) or Still Bay layers at the site. A recent study of carbon-nitrogen ratios in the Peers point, and a sample of Later Stone Age (LSA) and MSA faunal remains from this site, confirms that the point originates from MSA layers (d'Errico and Henshilwood 2007). A single bone point was discovered at Klasies River in layer 19 of Shelter 1a at the

Bone Tools, Paleolithic, Fig. 4 Selection of Châtelperronian bone tools from Grotte du Renne at Arcy-sur-Cure, France (*left*), and Uluzzian sites from Italy. (Images: d'Errico/Vanhaeren/Borgia)

base of the HP. A date of approximately 80–60 ka, centered on 70 ka, was suggested for the HP at Klasies River. The only other pointed bone implements known from the MSA come from Sibudu Cave. These items include a polished bone pin attributed to the late MSA, from layer Co with an age of ~35 ka, a second bone pin, from layer PGS, and a large bone point from layer GS. These two items occur in the HP sequence with age estimates >61 ka. In addition to a small spatula-shaped tool, the discovery of a collection of worked bone at Sibudu Cave (Backwell et al. 2008) confirms a bone tool industry for the Howiesons Poort technocomplex. Comparative microscopic and morphometric analysis of the large bone point from Sibudu with bone tools from southern African Middle and Later Stone Age deposits, an Iron Age occupation, nineteenth-century San hunter-gatherer toolkits, and bone tools used experimentally in a variety of tasks revealed that it is most similar to arrow points from LSA, Iron Age, and historical San

Bone Tools, Paleolithic, Fig. 5 Selection of barbed bone points from Katanda, Democratic Republic of the Congo, interpreted as harpoons used for fishing. (Images: F. d'Errico)

sites. This is interpreted, together with the extreme symmetry recorded in the tip of the Sibudu point, as a shift from the use of hand-delivered bone spearheads in the Still Bay (at Blombos) to bow and arrow technology in the HP. If confirmed, the bone point from Sibudu Cave pushes back the origin of bow and bone arrow technology by at least 20,000 years, substantiating arguments in favor of the hypothesis that crucial innovations took place during the MSA in Africa. The Sibudu bone point also falls within the morphological variability of a type of unpoisoned fixed bone arrow point used by Bushmen for hunting small game and birds, which is in accordance with the associated fossil fauna, represented mostly by small forest antelope.

African Later Stone Age

Projectile bone points and awls are associated with the Border Cave Early LSA assemblage, with an age of ~36 ka BP, and bone points similar to those known ethnographically occur at many LSA sites in southern Africa, including Rose Cottage, Oakhurst, and Nelson Bay caves, as well as Jubilee, Bushman Rock, and Giant's Castle Rockshelters (Deacon and Deacon 1999). Unlike MSA points, which were typically modified through scraping, LSA points evidence shaping through scraping and grinding. Later Stone Age bone tool categories include finely worked arrowheads, linkshafts, spatulas, polished needles, awls, fish hooks, gorges, and pegs, many of which are incised and decorated. The production of a range of tools from different raw materials is thought to imply increased technological and social complexity and the possible emergence of craft specialization. Later Stone Age bone tools are frequently associated with a suite of other innovations that include microlithic stone tool industries, rock art, and decorative items like beads and shell pendants. Formal bone tools, as with many of the innovations that became common in the LSA,

Bone Tools, Paleolithic, Fig. 6 Bone tools from the Middle Stone Age deposits at Blombos Cave. (Images: d'Errico/Henshilwood)

were already present, although rare, in the MSA. Grinding to shape formal tools is the only shaping technique that is virtually absent before the Later Stone Age.

Upper Paleolithic of Europe

This period is characterized by previously unseen complexity in the techniques used to manufacture bone artifacts, greater diversity in the raw materials used, and a proliferation of bone tool types and patterns used to decorate them (Camps-Fabrer 1988; Knecht 1993). During this period we also observe for the first time clear consistencies in the geographic distribution and association of bone tools, with some types widespread over large regions and others characterizing an area or a specific cultural facies. The Upper Paleolithic can be seen in this respect as a time in which all

Bone Tools, Paleolithic, Fig. 7 (**a**) Aurignacian split base point from Spy, Belgium; (**b**) Early Gravettian spear point from Mazière, Belgium; (**c**) fragment of a spear point with bladelet inserts, and spear point (**d**) from the Upper Magdalenian levels of Pincevent, France. (Images: courtesy M. Vanhaeren)

the bone/organic tools specific to hunter gatherers of high latitude appear and become established. Projectile point types, size, and the way in which they are prepared for hafting reveal a previously undocumented variability and complexity, suggesting the emergence of prey-specific and perhaps season-specific hunting equipment (Fig. 7). Evidence for the use of complex foreshaft and detachable projectile points appears at the beginning of the Upper Paleolithic and becomes more elaborate at the end of this period. Among the new tools that appear for the first time in this period, we find the boomerang – a specimen in mammoth ivory was discovered at Oblazowa, Poland, in levels dated to 23 ka BP (Valde-Nowak et al. 1987) – bone needles, spear throwers, and perforated batons at French sites dated to ~20 ka BP (Fig. 8). Harpoons made of reindeer and red deer antler become common in the Magdalenian ~13 ka BP (Julien 1982). Bone and antler tools used as soft hammers, pressure flakers, and punches used for intermediate percussion flaking also become common during this period. A number of tools used in hunting and domestic activities, typologically labelled as perforated batons, spatulas, pegs, and knives, still need to be investigated to elucidate their most likely functions.

Key Issues/Current Debates

A review of the literature shows that research interest in prehistoric bone tools has focused mainly on three areas. The first concerns verifying the existence, deciphering the functions of early hominin bone tools dated to between 1 and 2 Ma, and identifying who used them. The second area of interest concerns formal bone tools from MSA deposits in Africa, and whether they may be taken as reliable proxies for the emergence of modern humans and so-called modern behavior. The third relates to Upper Paleolithic bone industries and the reasons for the high degree of technical and symbolic investment in their production. The manufacture of bone and ivory implements using techniques specifically conceived for these materials, such as scraping, grinding, grooving, and polishing, is generally considered to be associated with modern human behavior and advanced cognition. A reason for this view is that the final shape of a bone tool manufactured with these techniques can be accomplished with a high degree of accuracy, which makes "formal" bone tools especially appropriate for inferring the degree of standardization and complexity of a technical system. Another reason is that the production of tools from a range of raw materials is thought to imply a diversified strategy of raw material acquisition and the possible emergence of craft specialization and increased complexity in social roles. A third reason for linking social and cognitive complexity with the presence of bone tools is the view that elaborated bone tools are a technological innovation associated with the spread of anatomically modern humans across Europe at the beginning of the Upper Paleolithic, forming part of the suite of critical inventions that followed this peopling

event. As such, Upper Paleolithic bone tool industries have been used to support the scenario of a cognitive revolution occurring in Europe at ~40 ka, but the discovery of bone awls and probable projectile points at a number of securely dated MSA sites in South Africa challenges this view.

International Perspectives

The emergence of bone technologies has traditionally been considered as coeval with the arrival of modern humans in Europe. Recent discoveries and reappraisal of old evidence reveal a more complex pattern, with two traditions of bone modification and utilization in South and East Africa during the Early Stone Age, convincing instances of bone shaping through percussion at a number of Acheulean and Mousterian sites from Europe, and the systematic use of bones as retouchers in the Lower and particularly Middle Paleolithic of Eurasia. Clear evidence of complex bone technologies is found at Middle Stone Age sites in sub-Saharan Africa, at late Neanderthal sites from France and Italy, and at early Upper Paleolithic sites from Europe, Siberia, and the Near East. Abundant and diverse evidence for the use of bone as a raw material is associated with most Upper Paleolithic cultures, starting with the Ancient Aurignacian at ~40 ka. The broad implications of this emerging pattern for the cultural evolution of our lineage have not been explored in detail, mostly because researchers focus their attention on a single topic, site, or time period. Outdated paradigms regarding the evolution of stone and bone tool technology appear to have become established in the literature and thus in the minds of many scholars. It is widely accepted, for example, that the development of technology was a gradual process that proceeded in parallel with biological evolution and that the early use of bone tools was essentially immediate, involving only a short series of single-stage operations, and thus a low degree of conceptualization. It is also thought that bone tools shaped by knapping simply reflect the transfer of the percussion flaking technique from stone to bone and that early humans were incapable of developing sophisticated techniques specifically conceived for bone. Multidisciplinary research in the fields of archaeology, primatology, paleoanthropology, ethnography, genetics, and radiometric dating indicates a different scenario. The Paleolithic record of bone and stone tools shows that hominin technological evolution advanced in a nonlinear manner and that from the outset bone tools exhibit signs of innovation, manifest as implements intentionally modified through knapping and grinding. Current findings are at odds with the idea that hominins of the genus *Homo* were the only modifiers of early bone tools and do not support the hypothesis that the manufacture of formal bone tools is the exclusive domain of behaviorally modern humans. The identification of a discontinuous pattern, with innovations appearing and disappearing, or being associated in a way that does not match the expected trend, supports the view that bone and complex lithic technology do not necessarily represent reliable hallmarks of "modern behavior" and cannot be attributed an unequivocal evolutionary significance. A paucity of sites that have been excavated or dated using modern standards makes it difficult to establish whether the apparent disappearance of cultural innovations, particularly when these are embodied in small, fragile items, is due to sampling, excavation methods, destructive taphonomic processes, variability in subsistence strategies, or a loss of previously acquired cultural traits. In order to explain the discontinuous pattern in hominin technological evolution and the trans-species phenomenon of bone tool utilization in prehistory, we need to evoke social, demographic, and climatic factors, and their potential impact on similar innovations among geographically dispersed populations in Africa and Eurasia.

Future Directions

There is a cogent need to promote collaborative interdisciplinary research, bringing together specialists from different research traditions to analyze material and find the most suitable ways forward. We need to combine technological and

morphometric attributes of bone tools to evaluate differences between sites and periods and identify regional clines and diachronic evolutionary trends. Finally, a georeference database of bone tool distribution across regions in which there are abundant sites with bone tool industries would assist in addressing the link between cultural and environmental change.

Bone, Trauma in

Erin H. Kimmerle
Department of Anthropology, University of South Florida, Tampa, FL, USA

Introduction

Forensic anthropology is playing an ever increasing role in medicolegal death investigations. Beyond osteological analysis in a laboratory setting, forensic anthropologists work with law enforcement agencies to search for clandestine graves, assist at crime scenes in the recovery of human remains and

associated evidence, assist medical examiners with trauma analysis in relatively recent cases, and conduct research, casework, and educational programs through academic settings. At the core of medicolegal death investigations are questions about cause and manner of death which may determine whether or not a crime was committed. Bioarchaeologists may apply a similar protocol of osteological methods to historic and archaeological populations for individual or population level trauma analysis. For forensic anthropologists who apply these methods to homicide investigations, the role is increasingly demanding as they are called to testify in court about human identification, interpretations about inflicted trauma, and the time since death.

Deaths resulting from traumatic injuries are better contextualized through the study of skeletal trauma. On an individual level, ante- and perimortem injuries provide details about a person's life and death, and healed trauma reflects injuries or events that occurred throughout a person's life while those occurring in association with the death event may indicate the manner of death. Across a population, the prevalence of trauma provides information about activities, mobility, warfare, and the general health of a population. Several comprehensive literature reviews and original studies are included in Grauer (1995), Larson (1997), Roberts and Manchester (2005), and Buikstra and Beck (2006).

The population approach has been more widely used in bioarchaeological research involving analysis of historic or archaeological populations. However, a population approach to documenting trauma is critical to war crime and genocide investigations in which establishing the scale and widespread pattern of injuries prove the occurrence of unlawful mass atrocities (Kimmerle and Baraybar 2008). Consequently, the analysis of trauma in bone has many applications for anthropological research today.

Historical Background

Skeletal trauma has been used to document injuries that occurred during a person's life (antemortem trauma) as it may be useful in human identification when antemortem records are available for comparison or show patterns of activity (Fig. 1). In traditional approaches, the process of documenting skeletal trauma has been largely descriptive and focused on fracture classification (Ortner and Putschar 1981; Mann and Murphy 1990; Buikstra and Ubelaker 1994; Galloway 1999). Increasingly, contextual information is incorporated into an interpretation of which injuries occurred and to some extent, the circumstances surrounding the event. Contextual information may include burial factors at the crime scene, clothing, associated artifacts, radiography and other scanning technologies, bone density, and histology (Brogdon et al. 2003; Kimmerle and Baraybar 2008; Komar and Buikstra 2008).

Bone, Trauma in, Fig. 1 Close-up view of left face showing healed, antemortem fractures to the nasal bones and maxilla

Key Issues

Terms and Concepts

Skeletal trauma is typically described by the mechanism of force: sharp, blunt, sharp-blunt, or projectile trauma (Table 1). Injuries resulting from gunfire (GSW) are categorically placed with blunt trauma as they produce a crushing force to the bone. However, for practical purposes, GSW

Bone, Trauma in, Table 1 Mechanisms of skeletal trauma

Category	Mechanism of force	Examples
Blunt trauma	Crushing, bending, twisting	Hammer, bat, club, crowbar, fist or foot (stomping)
Sharp trauma	Cutting, stabbing, puncturing	Knife or blade, saw
Blunt-sharp trauma	Crushing, cutting, hacking	Machete, axe, hatchet
Blasting trauma	Crushing, projectile, burning	Explosive ordinances, mortars, grenades, pipe bombs
Gunfire trauma	Crushing, projectile	Handgun, rifle, shotgun, submachine or machine gun

injuries are often uniquely categorized. Likewise, projectile trauma may include gunfire or explosives. Injuries resulting from explosive or blasting forces result from blunt trauma, projectile trauma, pressure changes, and burning. Increasingly, modern investigations into crimes occurring during conflicts include many examples of explosive injuries such as those resulting from the shelling of civilian populations, mortars, grenades, or other acts involving explosive devices. Since these types of injuries result from several mechanisms (i.e., projectile and blunt trauma), they are also often described in a unique category.

The timing of fractures or injuries is critical to correctly interpreting the circumstances surrounding the incident (Table 2). Trauma occurring at the time of death and in association with the death event is called perimortem trauma. Differentiating perimortem "injuries," "fractures," "defects," or "trauma" from postmortem "damage," "breakage," or "scavenging" is often highly scrutinized in court when one party wants to cast doubt on the timing of the injuries or the opinionated cause of death (Fig. 2).

The use of the terms "ante-" and "perimortem" trauma can also be confusing at times, since the pathologists occasionally combine "ante- and perimortem trauma" into one category of "antemortem." The difference is the presence of tissue

Bone, Trauma in, Table 2 Timing of fractures

Category	Morphological characteristics of fractures and/or defects
Antemortem (injury occurred prior to death and is NOT associated with the death event)	Fractures show signs of healing, i.e., porosity, new bone growth, callus formation, or infectious lesions
Perimortem (injury occurred at or around the time of death and IS associated with the death event)	Fractured margins are sharp and even. Bone may bend inward or away from direction of force. Radiating fractures from point of impact may be present
Postmortem	Damage to bone may include breakage, weathering, and erosion due to soils and water, or animal scavenging. Damaged margins tend to be uneven and rough in texture without evidence of radiating fractures. Bone elasticity is diminished and fractures are not consistent with "bending" quality of living tissue

Bone, Trauma in, Fig. 2 Postmortem breakage – an artifact of taphonomic processes, not inflicted trauma. (Modified from Kimmerle and Baraybar 2008)

reaction to the injured area, be it inflammation or repair, which does not have time to develop in the perimortem period. Usually, such determination can be based on microscopic rather than gross examination. An anthropologist, relying on skeletal evidence, also attempts to differentiate trauma

that occurred while a person was living (antemortem) from that which is associated with the death event (perimortem). This can be based on evidence of healing or patterns of the injury and its survivability. However, the window of timing would be typically wider than the one based on microscopic evaluation of inflammatory reaction, which has sequential pattern. Examination of skeletal remains usually would not inform directly about the mechanism of death, for example, hypovolemic/hemorrhagic shock and suffocation; however, it may be often reasonably inferred, and on occasion, microscopic findings at the injury site may be helpful.

In the course of homicide investigations, differentiating perimortem trauma from postmortem artifacts is important for determining the cause of death and other mitigating factors such as the intent to kill vs. wound or the atrociousness of the crime. In human rights investigations, such as those associated with modern conflicts, patterns of injuries may be indicative of specific crimes that are committed and differences are often observed among civilian causalities vs. genocide victims (Meddings 1997; Coupland and Meddings 1999; Michael et al. 1999). Due to protective clothing and the nature of modern combat, fewer casualties sustain gunfire injuries to the thorax. However, a group of casualties exhibiting multiple gunfire injuries to the thorax, shot back to front, are more likely civilians or executed soldiers rather than soldiers who were lawfully killed on the battlefield.

The protocol and methods used to identify, document, analyze, and present trauma are applied to both past (i.e., bioarchaeological) and current populations (i.e., forensic cases or war crime investigations) (see Table 3). However, the context, location, culture, and timing of the incident must be taken into account when approximating a specific weapon or the general circumstances around the mechanism of the injury. For example, a semi-patterned defect on a skull may be the result of blunt trauma. Determining the specific weapon used and context of events that occurred will depend on whether the skull relates to a recent homicide victim or, for example, a Roman soldier from the third century.

Bone, Trauma in, Table 3 Protocol for trauma analysis

Specific anatomical location
• Describe the bone, side, and aspect of each area affected
• Where necessary and/or possible, reconstruct bony fragments. Establish the number of injuries which may consist of one or more bone fractures/defects
Type of fracture and/or defect
• Simple or comminuted/complex
• Complete, incomplete, partial
• Linear, radiating, concentric
• Fracture line or defect: describe morphology, size, and location
• Mechanism of force such as crushing, compression, or twisting/spiral
Number of injuries
• This may be fewer than the number of fractures if one injury caused multiple bones to fracture
Sequence of multiple injuries
• To sequence multiple bone injuries, assess where the factures or evidence of injuries overlap one another
Direction and speed or "velocity" of force
• Use only very general or broad descriptions and avoid commenting on "velocity" in cases of GSW. The range of ammunition and types of weapons do not conform to allow a standard use of these terms
• Location of injuries should include bone, side, region, and aspect
• Direction of force should be broadly descriptive, i.e., "left to right" or "up to down"
Timing of injury
• Morphological characteristics of fracture margins (ante- or perimortem)
• Histological analysis of fracture margins for timing of injury
• Report any postmortem damage if present and differentiate from traumatic injuries
Documentation methods
• Draw, sketch, and photograph bones
• Document injuries both prior to and following cleaning, washing, or processing
• Radiograph bones and clothing
• 3D imaging through laser or CT scanning
• Microscopy of fractured edges, particularly useful for cut marks and sharp trauma
• Histology of fractured edges may assist with timing of injury (i.e., ante- vs. perimortem)

Understanding the context and accounting for a number of variables about the individual and population are important for creating the most accurate and comprehensive interpretation of events.

Bone, Trauma in, Table 4 Epidemiological approach to interpreting skeletal trauma

Demography (i.e., age, sex, ancestry of decedent)
Context (i.e., facts about the scene, modes of deposition, witness statements, crime scene forensic evidence such as blood patterns)
Location of death (i.e., public place or private residence)
Burial factors (i.e., primary or secondary crime scene/ burial location, buried or surface remains, use of containers for concealment)
Intent
Scientific protocols
Methods for differential diagnosis
Weaponry and ballistics science
Cause, manner, and mechanisms of death

Therefore, part of the protocol for interpreting skeletal trauma should include a range of factors as discussed in Table 4.

Interpreting skeletal trauma by direct examination of the skeletal remains reveals evidence that soft tissues or radiographs alone cannot always demonstrate. In some cases, the number of skeletal fractures is greater than the number of soft tissue injuries evidenced by an external examination of the body. In contrast, inflicted trauma resulting in death may consist of soft tissue injuries without the presence of skeletal fractures or defects. There is a misperception that without soft tissues, investigators are limited in their ability to reach definitive conclusions about the cause or manner of death. Even in cases where the specific cause of death is unknown (whether due to decomposition, the mechanism of injury or incomplete recovery), the manner of death may be homicide as evidenced by the circumstances of the death. In such cases, the context and other investigative facts combined with skeletal trauma enable a ruling such as "*homicide due to unspecified traumatic causes, homicidal violence*, or *battered baby/child syndrome*."

The morphology of skeletal trauma is shaped by internal (i.e., the particular area of bone affected), extrinsic (i.e., the type of weapon), and other factors (i.e., whether or not it resulted from act of volition). By reconstructing the bony fragments, information may be gained about the type of weapon, the number, and in some cases, the sequence of injuries. The critical first step is to differentiate perimortem trauma from postmortem or taphonomic artifacts. In other words, fractures that result at the time of death and may have contributed to the death have to be differentiated from animal scavenging, warping due to ground pressure for buried remains, surface weathering, or excavation damage (Fig. 2).

Documentation of Skeletal Trauma

The documentation of injuries should include a description of the specific bone/side/aspect affected and the particular features present such as the type of fracture or defect, its size, and extent. Skeletal trauma may consist of a fracture, dislocation, subluxation, or defect. Fractures may be classified as simple and complete, partial/ incomplete or "greenstick," comminuted, spiral, compression, depressed, hinge, or buckle. A number of references define and outline characteristics for each type of fracture, as well as the common eponymous fractures referred to in pathology (refer to Ortner and Putschar 1981; Mann and Murphy 1990; Buikstra and Ubelaker 1994; Galloway 1999; Kimmerle and Baraybar 2008; Waldron 2009).

Mechanisms of Injury

Once skeletal injuries are delineated, the morphology of wounds, defects, and fractures provides information on the mechanism of injury (Kimmerle and Baraybar 2008). The common mechanisms and general characteristics for each category are summarized below:

- Blunt Trauma
  - Characterized by an object that crushes tissue. Skeletal tissue bends and may have a depressed or bent appearance. If enough force is applied, the tissue will fracture.
  - An object may strike the individual or the individual may be expelled toward an object (i.e., a person's head hits the dashboard of a car during a motor vehicle accident).
  - Gunfire injuries and shrapnel or explosive injuries are forms of blunt trauma, but generally are categorized separately due to the amount of force and other characteristics

Bone, Trauma in, Fig. 3 Patterned cranial defect resulting from blunt impact. The ectocranial (**a**) and endocranial (**b**) views are demonstrated. (Modified from Kimmerle and Baraybar 2008)

Bone, Trauma in, Fig. 4 Patterned cranial defect with concentric and depressed fractures, resulting from blunt impact from a long, linear object. (Modified from Kimmerle and Baraybar 2008)

also involved with these mechanisms such as burning and the presence of shrapnel.

- Examples of objects resulting in blunt trauma include a fist, baseball bat, hammer, and floor (Figs. 3, 4 and 5).

- Sharp Trauma
  - A penetrating object that cuts tissues and bone.
  - May be associated with blunt trauma, particularly with hacking types of weapons such as machetes or axes. Hacking trauma is often classified as sharp-blunt trauma due to the amount and nature of the force applied as well as the characteristics of hacking instruments.
  - Sharp trauma includes different types of wounds: stabbing, incised, and puncture.
  - Stab and incised wounds to bone often result in cut marks, whereas puncture wounds may result in patterned defects depending on the instrument/weapon.
  - Sharp trauma such as cut or saw marks resulting from postmortem dismemberment should be carefully delineated as such. While it may not be possible to determine whether the person was alive

Bone, Trauma in, Fig. 5 Multiple blunt impacts to the right side of the skull, toward the posterior aspect of the cranium. Multiple points of impact evident by the depressed and concentric fracture patterns. (Modified from Kimmerle and Baraybar 2008)

Bone, Trauma in, Fig. 6 Anterior view of body of a cervical vertebra illustrating numerous linear cut marks, resulting from sharp trauma. (Modified from Kimmerle and Baraybar 2008)

Bone, Trauma in, Fig. 7 The lateral aspect of the distal articular surface of the left femur with multiple depressed and cut areas of bone resulting from numerous injuries with a machete. The presence of crushed, bent, and cut bone is indicative of hacking trauma. (Modified from Kimmerle and Baraybar 2008)

at the time of dismemberment if there is not clear evidence of the cause of death, it should be pointed out when sharp trauma is present in the form of dismemberment as opposed to incised or puncture wounds from cases of stabbing. The number, location, and type of sharp defects in the areas of major joints provide strong evidence of dismemberment.

- Many postmortem artifacts such as animal scavenging and surface cracking due to weathering may mimic sharp trauma.
- Examples include knife, axe, hatchet, machete, and glass (Figs. 6 and 7).

Bone, Trauma in, Fig. 8 Gunshot entrance wound, resulting from a handgun. The small circular defect has two very small radiating fracture lines (**a**) and (**b**). The bullet did not exit the skull but extended to the left side and ricocheted leaving behind gunshot residue evident in the radiograph

Bone, Trauma in, Fig. 9 Gunshot entrance wound resulting from an AK47. Note the larger diameter of the defect featured in Fig. 8 and the presence of radiating fractures. (Modified from Kimmerle and Baraybar 2008)

- Gunfire
  - Injuries characterized by a handgun, rifle, shotgun, submachine, or machine gun (Figs. 8, 9, 10, 11 and 12).
  - The class of weapon, general distance of shot (close vs. distant), number, and sequence of injuries may be determined from skeletal injuries.

Bone, Trauma in, Fig. 10 Gunshot exit wound. Note its irregular shape and the external beveling along defect margins. (Modified from Kimmerle and Baraybar 2008)

Bone, Trauma in, Fig. 11 Gunshot exit wound. Note the external beveling along defect margins and extensive fracturing. (Modified from Kimmerle and Baraybar 2008)

- Skeletal defects tend to be patterned and reflect the shape of the projectile. Therefore, bullets that hit bone perpendicular have a circular appearance with a diameter consistent with the size of the bullet. Projectiles that are irregularly shaped or hit the bone at an angle or tangentially will produce a sideways or irregular-shaped defect.
- Bullets that penetrate the body may fracture more than one bone and/or change direction within the body or calvarium, sometimes referred to as "ricochet." The number of wounds needs to be delineated from the number of injuries as one bullet may cause several wounds.

Bone, Trauma in, Fig. 12 Gunshot wound, through and through to rib showing entrance and exit sides of the bone with radiating fractures and beveling. (Modified from Kimmerle and Baraybar 2008)

- Blast Injuries
  - Creates thermal, blunt, sharp, and penetrating trauma (Fig. 13).
  - Shrapnel creates irregular-shaped penetrating defects in skeletal tissue and may become embedded in bone.
  - Skeletal defects and fracture morphology are largely affected by extrinsic factors such as the type and amount of explosive, location of the incident (i.e., in an enclosed space vs. outdoors), and the type of surrounding materials which may become projected shrapnel.
- Burning Injuries
  - Causes discoloration, fractures, bone shrinkage, and dismemberment.
  - Trauma inflicted prior to burning is still evident even after severe burning.
  - Burning may result from the incident at time of death, such as an automobile accident or explosion. Burning may also be used postmortem in an attempt to hide or destroy evidence.
- Evidence of Chronic Abuse, Neglect, or Torture
  - Skeletal evidence of prolonged abuse or torture has been used in domestic cases

Bone, Trauma in, Fig. 13 Shrapnel recovered from thigh region following mortar attack. The metal fragment (**A**) is shown next to the radiograph which depicts the fragment embedded in the bone (**B**)

involving children and the elderly and in international courts involving political detainees or prisoners of war.

– Evidence of chronic abuse includes multiple fractures in various stages of healing, nutritional deficiencies, malnutrition or starvation, untreated medical conditions, or insufficient health and dental care.

Uncovering Abuse When the Baby "Falls"

Six cases of child deaths from Lincoln, Nebraska, resulting from blunt trauma are compared to illustrate patterns of intentional vs. accidental trauma. Five of the six cases involved female victims, ranging in age from several months to 3 years. Of these cases, five were homicides and one was an accident. Among the homicides, three parents reported that the infant "fell" accidentally upon seeking medical treatment for their children. Victims in all cases had multiple blunt injuries throughout the body: head trauma (5/5), neck (2/5), chest (2/5), abdomen and back (1/5), and extremities (4/5). In all cases, brain trauma was present, though only one case exhibited cranial fractures. Further, in only two cases was evidence of prior neglect or abuse present. In all cases, medical intervention was sought. Survival time ranged from 27 min to 4 days. The amount of activity among victims immediately following the injury ranged from immediate incapacitation to full activity/movement and alertness. The infant who survived the longest had shown the most amount of activity following the injury but went into cardiac arrest three days after the incident. In only one case were there no signs of trauma visible externally.

The only male victim (10 months old) suffered the greatest amount of injuries with multiple traumas to each region of the body. He further suffered a 5.2-cm cranial fracture and two fractures to the seventh and eighth ribs that were in the process of healing, thereby showing evidence of a prior incidence of abuse. Three soft tissue injuries were evident on the face and back of the head. In this case, the infant had soft tissue injuries evident on the abdomen and back with associated organ damage in the abdomen. It was alleged that the infant "fell" from the arms of his mother's boyfriend. In a second case, the infant reportedly "fell" in the bathtub yet was found to have soft tissue injuries on the head, face, buttocks, and hand, including human bite marks. This infant also had a 25-g subdural hematoma (pooling of the blood in the space between the dura and meninges or outer and middle layers of the brain covering) but no skeletal fractures.

It is common in cases of child abuse that the parent or caregiver tells authorities that the child fell or had an accident, even while seeking medical treatment for inflicted trauma (Kimmerle and Chrowstowski 2011). Therefore, it is incumbent upon investigators, medical examiners, and forensic anthropologists working on such cases to present clear evidence that will either support or refute such claims. Investigators had such a case when a 10-month-old male infant was taken to the emergency room by his father. It was alleged that the infant fell from the father's arms and hit his head on the floor. The infant sustained multiple injuries on the head, neck, chest, abdomen, and back, including multiple brain injuries. Postcranial fractures were present but no skull fractures were present. In this example, investigators had all lines of possible evidence open for interpretation. Since medical intervention was sought, there was abundant documentation about the injuries at the time of autopsy. However, this is not always the case, when the remains of abused children are hidden or

Bone, Trauma in, Table 5 Differential case factors for accidental versus inflicted trauma in comparative baby death cases

Factors	Case I	Case II	Case III
Manner	Homicide	Homicide	Accident
Circumstances	Reportedly fell from arms of caretaker	Reportedly fell in bathtub	Fell downstairs
Demography	10-month-old male	3-year-old female	1-year-old female
Injury location	Head, neck, chest, abdomen, back, extremities	Head, extremities	Head, extremities
Survival time	8.5 h	46.9 h	78 h
Amount activity	Immediately incapacitated	Immediately incapacitated	Unknown
Skeletal fractures	Skeletal fractures	No fractures	No fractures
Prior evidence of abuse	Fractures in various stages of healing	None	None

buried. In such cases, it may be years before the remains are uncovered and the incidence is investigated. When this occurs, it may be that skeletal trauma is the only physical evidence present to support or refute allegations of abuse.

The injury occurred at 7:00 am and the infant died at 3:30 pm, having survived 8½ h with medical intervention. Immediately following the injury, the infant was incapacitated and never exhibited any sign of physical activity. The postmortem examination revealed healing fractures from prior injuries. In Table 5, the epidemiological factors for three cases are presented, the case study discussed here and two comparative examples which illustrate some of the epidemiological variants present. All three cases represent infants, ages 10 months to 3 years, who either died as a result of a fall or were reported to have "fallen." In a comparative case (Case 2), the death was reported to have resulted from injuries the 3-year-old child received after falling in the bathtub. Further investigation of witness statements and an autopsy revealed in fact this was a case of abuse and it was ruled a homicide. In contrast, Case 3 consists of a 1-year-old female who fell and died of her injuries several days later. There was no history or indication of abuse, and the manner of death was ruled an accident. In all three cases, the children died of blunt trauma and all three sustained brain trauma, though only one case exhibited skeletal fractures (Case 1).

Bone, Trauma in, Fig. 14 Fragmented bone remains with clothing recovered from outdoor crime scene in snow

Establishing Cause and Manner of Death

The skeletal remains of a 20–30-year-old male along with clothing, a shotgun, pellets, and a shell casing were recovered in a remote, wooded area along a roadside during the winter months (Fig. 14). The bones of the face, cranial vault, and mandible were fractured (Fig. 15). The fracture patterns and scalloped edges along the fractured margins of the left temporal, frontal, and occipital bones were indicative of a shotgun injury. Further, the fractured edges and semicircular defects were the same color and texture as the rest of the bone and were consistent in appearance and morphology of perimortem injuries.

The maxilla was completely fractured along the palatine suture and bilaterally in the transverse

Bone, Trauma in, Fig. 15 Fragmented cranial vault (left lateral view) following near contact shotgun wound to the mouth. Note the scalloped edges along the inferior fractured margins

Bone, Trauma in, Fig. 17 Fractured palate showing shotgun entrance wound

Bone, Trauma in, Fig. 16 Maxilla and mandible of shotgun case. Pellets entered through the open mouth

Bone, Trauma in, Fig. 18 Left mandible showing fractured condyle and ramus following shotgun wound to the mouth

plane inferior to the zygomatic processes (Fig. 16). The palate exhibited an irregular-shaped defect (Fig. 17). The mandible was bilaterally fractured in between the mandibular body and ascending rami. The left coronoid process was also completely fractured from the ascending ramus of the mandible (Fig. 18). The specific fracture patterns and defects present in this example demonstrate the causative agent while the manner of death is determined based on associated evidence and the police investigation. In this case, there was a single shotgun wound in the face and cranium, from front to back. While the mechanism of death may not be known without the presence of soft tissues, the cause of death is inferred from the shotgun wound to the head. Based on circumstantial information, the manner was ruled a suicide.

International Perspectives

Illegal detainments, torture, and extrajudicial executions are some of the most common forms of human rights violations throughout the world. They can also be some of the most challenging

cases to prove as victims tend to "disappear" and cases may not be investigated until many years after the fact. International and local investigations for the prosecution of torture, war crimes, and genocide rely heavily on forensic anthropological and pathological evidence of perimortem injuries for these same reasons (i.e., examples tried by the International Criminal Tribunal for the Former Yugoslavia (ICTY): *The Prosecutor v. Rutaganda (ICTR-96-3), The Prosecutor v. Krstić (IT-98-33)*, and *The Prosecutor v. Brdjanin and Zupljanin (IT-99-36)*). For example, in the case of the *Prosecutor v. Limaj* et al. *(IT-03-66), Milutinovic* et al. *(IT-05-87), Popovic* et al. *(IT-05-88)*, skeletal evidence of torture was critical at trial. Numerous factures throughout the ribs and limbs exhibited bone remodeling in various stages of healing dating from weeks to months, thereby demonstrating evidence of repeated beatings (blunt trauma) during the period of detainment (Kimmerle and Baraybar 2008). Additional injuries in the form of skeletal defects resulting from gunshot wounds to the head and body showed no evidence of healing and were classified as perimortem trauma, proving the cause and manner of death was homicide due to multiple gunfire injuries. In this example, skeletal injuries provided evidence that several crimes were committed including torture and homicide.

Collectively, the body of research into skeletal evidence used to document torture is limited. A review of extrajudicial executions from various published reports and publications from Central and South America and the Balkans were discussed in Kimmerle and Baraybar (2008) representing a collective sample of 45 cases. In all of these examples, the mechanism of death was attributed to blunt trauma (BFT), sharp-blunt trauma (i.e., machete), or gunfire injuries (GSW) associated with some form of BFT resulting primarily from beatings prior to death. The type and location of skeletal fractures are documented, including evidence of antemortem fractures that were in various stages of healing at the time of death. In most cases, individuals were detained prior to death and the history of abuse reflects torture as documented by the associated medicolegal death investigations. Among the cases reviewed from the literature, BFT was the most common mechanism of injury (77.7%), followed by gunshot wounds (66.6%), and sharp-blunt trauma (24.4%). The overall distribution of fractures illustrates that the thorax is most commonly affected (64.4%), followed by the skull (35.5%), arms and legs (2.0%), and lower back (0.04%). Several other interesting patterns were noted:

- All cases of documented torture involved males, aged 14–68 years.
- These cases typically represented enforced detainment, repeated beatings, and finally murder.
- All cases with fatal gunshot wounds also had blunt trauma from assault to the ribs and sternum, indicating beatings prior to death.
- Almost 78.0% of cases of extrajudicial execution involved BFT to the chest, indicating beatings prior to death.
- In four of these cases, individuals also had previous fractures in various stages of healing – further indicating torture during their detainment prior to the fatal attack.

Evidence of sharp-blunt trauma was present in 11 cases involving machetes. Interestingly, among these cases, the arms and legs were also injured in addition to the thorax. "Defensive wounds" on the forearms and hands were present in 81.8% (9/11) of cases. Only 35.5% of cases involved the skull, but among these, gunshot injuries were also present in addition to blunt force injuries. It is important to note that the context is critical when trying to summarize trends such as these. In cases involving machetes, gunshot wounds were typically not present. Therefore, if one considers only cases with blunt force or gunfire injuries, the overwhelming majority of extrajudicial executions (88.2%) include both mechanisms of injury.

Population level analyses of trauma may also provide evidence of the particular type of crimes committed and will be critical in attempting to prove cases of genocide and war crimes. Specifically, injuries that are widespread demonstrate patterns of abuse or maltreatment, such as the ubiquitous machete trauma present in the 1994 Rwandan genocide which provides evidence of the intent to kill civilians outside the context of lawful warfare.

Future Directions

Today, methods used in forensic anthropology and bioarchaeology document physical evidence of the patterns of crimes committed and increasingly provide critical evidence at trial. There is need for further research in the areas of skeletal trauma, histological timing of fractures from degraded bone, and the ways in which paleopathology and population studies can be used for analyses of modern populations. Increased research and education with specific regard to international applications will further help improve best practice standards and expand the role of forensic anthropology in criminal investigations.

Bone: Chemical Analysis

M. Anne Katzenberg
Department of Anthropology and Archaeology, University of Calgary, Calgary, AB, Canada

Introduction

The general structure and chemical composition of bone are similar for all individuals, but there is some tolerance for minor variation in the elemental and isotopic composition of both the organic

and inorganic components of bone tissue. This variation is tied to the local environment and to the diet. Both trace elements and stable isotopes act as natural tracers that provide information to archaeologists about details of the lives of past people, including diet, place of residence, and migration. Bone is a porous material composed of small crystals of hydroxylapatite. This small crystal size is beneficial in life since the bone is a storehouse for calcium and phosphorus. Bone mineral can quickly be mobilized from the skeleton when needed for physiological functions. From the perspective of the archaeologist, the small and poorly formed crystals are not an advantage because buried bone picks up and exchanges chemical constituents with the surrounding soil and water. Tooth enamel is also composed of hydroxylapatite but with larger crystal size and less organic content. Following early attempts to use chemical variation in the bone as a source of information about the past, studies of trace elements have largely been abandoned due to concerns about chemical exchange in the burial environment. Studies of stable isotopes in bone collagen from archaeological human bone have grown enormously since the early studies in the 1970s. Much of this research has been presented in edited volumes by Price (1989), Sillen and Armelagos (1991), Lambert and Grupe (1993), Bocherens et al. (1999), Ambrose and Katzenberg (2001), and Koch and Burton (2003) which resulted from the Advanced Seminars on Paleodiet.

Definitions

Bones are the skeletal elements that provide structural support for the vertebrate body. "Bone" refers to the tissue that makes up bones. That tissue has both an organic (approximately 30%) and an inorganic (approximately 70%) component. The organic component is predominantly collagen (90%), a structural protein, and a small amount of other proteins, collectively referred to as non-collagenous proteins. The inorganic component of the bone is made up of hydroxylapatite, a calcium phosphate mineral [$Ca_{10}(PO_4)_6(OH)_2$]. The chemical analysis of the organic component of the bone most often refers to the study of stable isotopes of elements included in the collagen, such as carbon, nitrogen, and sulfur. The chemical analysis of the inorganic component of the bone refers to the analysis of trace element substitutions in hydroxylapatite and their isotopes, and stable isotopes of carbon and oxygen in the carbonate (CO_3), that substitutes in minor quantities for phosphate (PO_4), an additional source of oxygen. Most trace elements substitute for calcium and are chemically similar to calcium These include other alkaline earth elements such as barium and strontium, and lead, which is not an alkaline earth element. Some trace elements, such as strontium and lead, may be measured for overall quantity (elemental analysis) and for stable isotope variation. Strontium isotopes are used as environmental tracers in migration studies, and earlier studies of strontium as a trace element remain important because they explain how strontium, and therefore strontium isotopes, find their way into bones and teeth from environmental sources.

Stable isotopes are variant forms of an element with the same number of protons and electrons but varying numbers of neutrons. Unlike radioisotopes, stable isotopes do not decay, so their quantity in a substance does not change over time. For most elements, one isotopic form predominates with very minor quantities of other isotopes. For example, 99% of all carbon occurs as ^{12}C with 1% ^{13}C. Nitrogen occurs as ^{14}N (99.6%) and ^{15}N (0.4%), while there are four stable isotopes of sulfur (Fry 2006). Stable isotope ratios for carbon, nitrogen, oxygen, and sulfur are usually expressed using delta notation as follows:

$$\delta \text{in‰} = \frac{R_{(\text{sample})} - R_{(\text{standard})}}{R_{(\text{standard})}} \times 1000$$

where R = the ratio of the number of heavier to lighter isotopes.

Due to the difference in the number of neutrons, the isotopes of an element have different

atomic weights and, therefore, react slightly differently in chemical reactions including those associated with physiological functions. This results in changes in the ratio of the heavier and lighter stable isotopes from one step to another in biochemical processes such as photosynthesis, digestion, and tissue formation. Details on stable isotope terminology, measurement, and standards can be found in textbooks by Fry (2006) and Hoefs (1997).

Carbon is found in both the organic and inorganic components of the bone. In hydroxylapatite, carbonate substitutes for phosphate in minor quantities (approximately 5%). Oxygen isotopes may be measured from carbonate or phosphate.

Trace elements are chemical elements that occur in minor quantities in a substance. Prior to the development of more sensitive analytical equipment, trace elements were defined as those present in quantities too small to be measured. With more sensitive instruments, trace elements can be measured and are normally present in parts per million (ppm) or parts per billion (ppb). In bone, trace elements from group two of the periodic table often substitute for Ca in hydroxylapatite. Such elements include magnesium (Mg), strontium (Sr), and barium (Ba). Strontium isotopes are most often measured in tooth enamel rather than the bone due to concerns about post-depositional exchange (diagenesis). Strontium has several natural isotopes, and the ones used in archaeological studies are ^{87}Sr and ^{86}Sr. The former is referred to as radiogenic strontium since it forms from the decay of ^{87}Rb. Therefore, measurements of strontium isotopes are not termed "stable" isotopes, but simply strontium isotopes or radiogenic strontium.

Instrumentation

Stable isotopes of lighter elements such as carbon, oxygen, hydrogen, nitrogen, and sulfur are analyzed on a light isotope mass spectrometer (Katzenberg 2008). Heavier elements such as strontium are analyzed on a solid source mass spectrometer also referred to as a thermal ionization mass spectrometer (TIMS).

Key Issues

Diet Early studies in both trace element and stable isotope analysis focused on determining diet and dietary change over time. The trace element strontium was known to vary between plants and animals given constant background levels, based on studies in health physics (reviewed by Burton 2008). Researchers interested in the relative contributions of plant and animal foods in the diet attempted to analyze strontium as well as strontium/calcium ratios in prehistoric human skeletal remains to chart dietary change. Burton and Wright (1995) demonstrated that the relationship between strontium in bone and dietary input is not linear. While trace elements are no longer the method of choice for paleodiet studies, the information gained from these studies is critical for reasonable interpretation of strontium isotope data used in migration studies.

Stable carbon isotopes were first studied by archaeologists interested in the introduction of maize in the diets of people in the Americas. Maize consumption is evident in bone collagen since maize is a C_4 plant and therefore contains more ^{13}C relative to ^{12}C in comparison to C_3 plants. Economically important plants which use the C_4 mode of photosynthesis include maize, millet, sorghum, and sugarcane. These plants are adapted to hot and dry conditions. Most plant species growing in moist conditions follow the C_3 mode of photosynthesis and contain relatively less ^{13}C to ^{12}C. The difference in the stable carbon isotope ratio ($\delta^{13}C$) in these plant types is passed along to consumers. This was first demonstrated in the 1970s by Vogel and van der Merwe (1977) with numerous applications subsequently (see reviews by Katzenberg 2008; van der Merwe 1982). Plants obtain carbon from atmospheric carbon dioxide (CO_2). Organisms from the ocean obtain their carbon from dissolved carbonate in seawater, which is enriched in ^{13}C in comparison to atmospheric CO_2; therefore $\delta^{13}C$ values are higher in marine organisms, and this difference is passed on to consumers. This was first demonstrated by Tauber in 1981 and Chisholm and colleagues in 1982 with subsequent applications by many scholars.

Stable isotopes of nitrogen have been used to explore trophic level differences in diet. There is enrichment of the heavier isotope (^{15}N) with each step in a food web (Minigawa and Wada 1984). In a terrestrial environment, leguminous plants generally have lower $\delta^{15}N$ values than non-leguminous plants. Animals feeding on plants will have $\delta^{15}N$ values approximately 3‰ higher than their food. Carnivorous animals will exhibit an additional 3‰ increase, and omnivores will have values intermediate with respect to carnivores and herbivores. Unfortunately this is not always the case as there are additional variables to consider. As is true for all stable isotope studies, the source of nitrogen determines the $\delta^{15}N$ values at the base of the food web. Fertilizers used to provide nitrogen to growing plants will have an impact on plant $\delta^{15}N$ values, which, in turn, influence $\delta^{15}N$ values higher up the food web. For example, the use of manure will raise the $\delta^{15}N$ value of nitrogen available to plants. Because of such variables, it is important to analyze potential food items in addition to human skeletal remains when attempting a dietary reconstruction. In aquatic and marine systems, $\delta^{15}N$ values also increase with trophic levels, but there are more steps in the food web, resulting in very high $\delta^{15}N$ values in aquatic and marine mammals and piscivorous fish. This makes it possible to use stable nitrogen isotopes to investigate the relative use of terrestrial and aquatic or terrestrial and marine foods in dietary reconstructions (e.g., Coltrain et al. 2004; Katzenberg et al. 2012).

Stable isotopes of oxygen have been used to study mobility in prehistoric societies. The tissue of choice for oxygen isotope analysis is tooth enamel (e.g., Buzon et al. 2011), but some studies have also been carried out on the phosphate in hydroxylapatite (e.g., White et al. 2007). Oxygen isotope ratios in human tissues reflect ingested water, and oxygen isotopes in water vary due to latitude, altitude, and distance from the coast (Bowen et al. 2005).

Strontium isotopes have also been used in mobility studies as they reflect the underlying bedrock in a region. Derived through food and water, strontium isotope studies must consider both the regional geology and the diet. Unlike the other isotopes discussed so far, strontium isotope studies do not use the delta notation. Instead, the ratio of $^{87}Sr/^{86}Sr$ is simply expressed as a number, usually to five significant decimal places depending on the precision of the analytical instrument (Bentley 2006). Strontium isotopes have been used to study migration in many regions of the world with increasing baseline data becoming available. Often, oxygen and strontium isotopes are both used to provide two perspectives for assessing mobility.

With the increasing use of isotopic data to explore residence and migration in archaeology and ecology, researchers have described "Isoscapes," or isotope maps (West et al. 2010 and chapters therein and Grupe and McGlynn 2016 and chapters therein). This global and interdisciplinary cooperation allows researchers to use existing isotope data for comparison when identifying nonlocal individuals and suggesting where they may have come from based on complementary sources of information such as shared cultural complexes or known seasonal migration patterns.

All bone chemistry studies are based on chemical tracers that are taken up during life. However, bone is a porous substance, and researchers must always perform tests to determine whether chemical tracers have been altered in the burial environment. The chemical exchange that can occur after death is referred to as diagenesis. For studies of bone collagen, preservation is assessed from the percentage of carbon and nitrogen in the sample and from the ratio of carbon to nitrogen (C/N) in the sample. Well-preserved collagen has a C/N ratio of 3.2. Some tolerance for variation is allowed, but most researchers reject samples if the C/N falls below 2.9 or exceeds 3.6 (Ambrose 1990). For bone mineral, it is more difficult to assess diagenesis (Burton 2008). Some researchers use infrared spectroscopy to evaluate the crystallinity of the bone. Normally the bone is poorly crystallized in comparison to hydroxylapatite in the earth, but with exchange in the burial environment, bone may become more crystallized, and the relative amounts of calcium and phosphate my shift. Improvements in methods to detect diagenesis are ongoing (e.g., Willmes et al. 2016).

Future directions of bone chemical research in archaeology involve increasing knowledge of other isotopic systems such as sulfur and hydrogen. Stable isotopes of sulfur are useful in detecting marine versus terrestrial foods in the diet, but sulfur is present in very low quantities in bone collagen. Increasingly sensitive analytical instruments have made it possible to analyze such isotopic systems in smaller quantities. Stable isotopes of hydrogen and oxygen have been used in wildlife studies for tracking movements, and the same types of studies can be done with humans (Bowen et al. 2005; Ehleringer et al. 2010). Other improvements in analysis include the use of laser ablation to isolate small regions of a sample, such as parts of a tooth, to analyze seasonal variation in diet (Sponheimer et al. 2006).

Bone: Histological Analysis

Christian M. Crowder[1] and
Victoria M. Dominguez[2]
[1]Office of Chief Medical Examiner, New York City, NY, USA
[2]Division of Anatomy, The Ohio State University, Columbus, OH, USA

Introduction

The analysis of hard tissue (bone and tooth) can be approached on many levels, ranging from the macroscopic to the molecular level. Intermediate to this range is the tissue level or histological level of organization. By definition, *histology* means *the science of the tissues*. More specifically, *histological analysis* is the study of the microscopic anatomy of tissues in plants and animals. Thus, histological analysis requires specialized equipment to prepare tissues for analysis and to magnify structures, making them visible. There are two analytical approaches used in anthropology when studying microstructures. One, referred to as histomorphology, is the qualitative analysis of microstructure morphology and organization. The other, referred to as histomorphometry, is the quantitative study of the microscopic organization and structure of tissue. These analyses can be performed using a static or dynamic approach to studying tissue. Static histological analysis allows for the evaluation of a tissue at a particular point in time. For example, anthropologists typically study histological samples from deceased individuals, which would only provide an assessment of the tissue at the time of death. Dynamic histological analysis allows for the evaluation of bone over a period of time. In order to observe microstructural responses using this method, analysis is performed in vitro or in vivo and the subject is exposed to various labeling techniques for histological tracking of cells. Regardless of the approach, histological analysis is an essential tool in many disciplines outside of medicine and biology.

The histological analysis of hard tissue within the discipline of anthropology has been used to study historical human remains from archaeological sites, as well as to assist with modern forensic investigations. Through histomorphology and histomorphometry, anthropologists are able to develop techniques to distinguish human from nonhuman bone, estimate age at death, evaluate biomechanical load history, assess skeletal health, and categorize pathological conditions. To fully interpret the information gathered through these techniques one not only needs to appreciate the limitations of evaluation methods, but more importantly have an understanding of the biology underlying the creation of histomorphological structures and the intrinsic and extrinsic factors that affect bone (or tooth) microstructure.

Bone is a dynamic tissue, constantly changing over an organism's life and providing a record of structural, mechanical, and compositional changes that anthropologists study in order to interpret the biological information hidden within. Teeth, with their hard enamel, are the most likely remains of an organism to endure through time. While a wealth of information is stored within the histological structure of teeth, the following text will be limited to discussions regarding cortical bone histology. For further reading about dental histology and its use within anthropology, see Guatelli-Steinberg and Huffman (2011).

Key Issues

Bone Biology and Cortical Bone Histomorphology

At the gross level, bone classifies as either cancellous (trabecular) or compact (cortical). Cancellous bone is porous, consisting of a network of thin spicules called trabeculae. Cortical bone is densely mineralized and relies on a vascular system to pass oxygen, nutrients, and waste in and out of bone. At the histological level, there are two basic bone types, woven and lamellar. Woven bone is laid down quickly; a structurally weak temporary construct of poorly organized collagen fibers and mineral crystals (Fig. 1). Lamellar bone takes longer to form but is stronger than woven bone due to its highly organized "plywood" arrangement of collagen bundles (Fig. 2). Embryonic skeletal development consists almost wholly of woven bone, which is slowly replaced by lamellar bone as an individual grows. As such, woven bone occurs rarely in the adult skeleton, except at sites of fracture healing and/or pathological conditions.

Mature compact bone is comprised of Haversian systems, which are characterized by uninterrupted, centripetally deposited lamellae surrounding a centrally located Haversian canal. The layers of concentric lamellae connect to each other via Volkman's canals, which are smaller and run at oblique angles to create a network for circulating blood and nutrients throughout the bone. Complete Haversian systems are bordered by a scalloped reversal line and are also known as secondary osteons (Fig. 3). Secondary osteons are a product of bone remodeling (bone turnover).

Two main processes directly shape bone, modeling and remodeling. In modeling, bone is removed in one location and added in another. Through periosteal and endosteal formation and

Bone: Histological Analysis, Fig. 1 Histologically, woven bone is characterized by wide spaces and poor organization. It is found in immature bone and at the sites of fracture repair or pathological conditions. (Pig rib at 100× magnification)

Bone: Histological Analysis, Fig. 2 Lamellar bone is characterized by organized, parallel bands of bone. The secondary osteons are signs of remodeling in these lamellae. (Human rib at 200× magnification)

Bone: Histological Analysis, Fig. 3 Human Haversian bone showing secondary osteons. (Human femur at 100× magnification)

resorption, bone modeling modifies bone size, shape, and relative orientation (Maggiano 2011). Bone remodeling, or internal bone turnover, is the process of continuous removal of older bone with the replacement of new bone throughout life. It occurs through the localized coupling of osteoclasts and osteoblasts forming an assembly of cells called the basic multicellular unit, or BMU (Frost 1969). Active BMUs follow a pattern of activation, resorption, and formation of bone known as the A-R-F sequence (Martin et al. 1998).

Unlike bone modeling, remodeling generally does not affect the overall size and shape of the bone. Bone remodeling is often described as having two functions: microscopic fracture repair and maintaining metabolic homeostasis of the bone matrix. Microscopic fracture repair is likely the primary function of bone remodeling, allowing the skeleton to adapt to its mechanical environment by reducing the risk of fractures and repairing damage created by repetitive cycles of mechanical loading (Burr 2002). Both modeling and remodeling can occur on the four bone envelopes: the periosteal, Haversian (intracortical), endosteal, and trabecular surfaces (Frost 1969, 1987; Parfitt 2002). Because each envelope is distinct, modeling and remodeling can occur at different times, rates, and magnitudes within the bone.

Applications of Bone Histology in Anthropology

Anthropologists are increasingly performing histological analysis to study both ancient and modern bone. As with other anthropological analyses of bone, the interpretation of histological results must be made within the context of skeletal biology. Histological analysis of skeletal remains in anthropology is applied to (but not limited to) the following categories: the differentiation of human from nonhuman bone, constructing the biological profile, reconstructing habitual activities or traumatic episodes in life, and the diagnosis of pathological conditions including an overall assessment of skeletal health. The following provides a brief summary of each type of analysis.

Human Versus Nonhuman

In instances where bone is too fragmentary, too weathered, or in some other way rendered unidentifiable by macroscopic observation, histological analysis can serve to differentiate human from nonhuman bone. Histological methods are less destructive, easier to perform, and less expensive than DNA analysis for distinguishing human from nonhuman bone. The typical method to differentiate human from nonhuman bone is to evaluate specific qualitative microstructural traits considered distinctive of nonhuman species. Researchers attribute two particular features of bone microanatomy to nonhuman species, plexiform bone and osteon banding. Plexiform bone is a fibrolamellar bone type described as having a "brick wall" appearance, a result of the linear vascular spaces that separate the lamellar "bricks" when plexiform bone is viewed in cross section (Martin et al. 1998: Fig. 4). Osteon banding is defined as distinct rows of five or more primary and/or secondary osteons, which often alternate with bands of lamellar bone (Mulhern and Ubelaker 2001).

In the absence of these easily observable and definitive nonhuman features, morphological characteristics of secondary osteons are often considered. Bone deposition and remodeling processes are similar in human and nonhuman mammals, making secondary osteons a prevalent feature of bone microstructure in most animals.

Bone: Histological Analysis, Fig. 4 Plexiform bone is brick-like in appearance and characteristic of non-human bone. (Pig humerus at 100× magnification)

Early research focused heavily on size differences in human and nonhuman microstructure, but provided little in the way of broadly applicable methods for identifying human or nonhuman material. Jowsey (1966) established that secondary osteon size varied across species and that there are age-related changes in Haversian canal size. More recently, it has been shown that human osteons tend to be elliptical, whereas nonhuman osteons tend to be circular. This supports anecdotal evidence that nonhuman osteons appear more circular than human osteons, suggesting that circularity may be a key variable to differentiate human from nonhuman Haversian bone. While histomorphometric data (i.e., osteon area and osteon circularity) appear promising for differentiating human and nonhuman bone, current methods lack sufficient validation and should be used with caution.

Constructing the Biological Profile

In anthropology, constructing a biological profile for unknown skeletal remains consists of a series of analyses that include the estimation of sex, age, ancestry, and stature, as well as the recognition of pathological conditions. Within forensic anthropology, the biological profile may be used in two ways: the first is to provide biological information that may be used to support the identification of an individual and the second is to use the information to narrow a potential missing person's list to streamline investigations involving unknown human remains. Outside of forensic applications, the biological profile is used to construct the demographics of ancient human populations (paleodemography). Considering the components of the biological profile, the estimation of age currently constitutes the majority of histological research in anthropology. While histological methods have not been used to estimate sex or ancestry, research has demonstrated that a relationship between histological variables and these factors likely exist. Although research suggests allometric relationships (e.g., relationship of body size to shape) with histological structures, stature estimation is not within the scope of histological analysis. Therefore, this section discusses histological age estimation with consideration of sex and ancestry as contributing factors in histological variation.

Age Estimation

The estimation of age at death is an essential part in the reconstruction of population demographics and the individual analysis of human remains. Estimating the age at death of children and young adults can be performed with greater accuracy owing to methods that are based on the growth and development of the human skeleton. Skeletal growth and development are regulated by endocrine and genetic factors producing biological age indicators that have a more predictable relationship with chronological age. The estimation of age at death for adults, in most cases, demonstrates a progressive decrease in accuracy as chronological age increases. Most methods for adult age estimation are based on degenerative changes of the skeleton, which can vary between individuals, geographic populations, and ancestral groups. The premise of histological age estimation is based upon clinical and anthropological research demonstrating that bone turnover occurs in cortical bone at a predictable rate over an individual's lifetime. As turnover occurs over time, the relative density of secondary osteons will increase, which should be evident until remodeling rates begin to fluctuate during the later decades of life (Fig. 5).

Bone: Histological Analysis, Fig. 5 Mean osteon population density (OPD) values for a known age sample separated into age cohort showing the relationship of OPD with age

Since the introduction of the first quantitative histological approach for the estimation of age at death by Ellis Kerley in 1965, histological parameters of age-related bone turnover have been well-documented in the anthropological literature for various skeletal elements. Crowder (2005) reviewed some of the most frequently employed methods, determining that the assessment of bone histology is a useful method for estimating age, producing accuracy values that are comparable to many gross morphological methods. Considering the myriad of methods, only a few have received significant attention within the field culminating in multiple validation studies applied to archaeological, cadaveric, and forensic samples. Regardless of the method, analysis involves evaluating a cross section or portion of a cross section of bone at the histological level and collecting variables that exhibit a relationship with chronological age. As with any method, it is imperative to perform the analysis as it is described in the literature.

Current methods typically quantify the amount of intact or fragmentary osteons within the cross section or region of interest within a cross section. More recently, histologists have turned to osteon geometry (i.e., shape and size) as an age indicator creating new approaches to the analysis of bone. Two variables that have received considerable attention are osteon circularity and area, which have both been found to correspond with age. Osteon circularity examines the geometry of the osteon in relation to a circle. Osteon area establishes the amount of bone area within the reversal line of an osteon. Research has indicated that mean osteon area decreases and circularity increases in older individuals; however, the control mechanisms for osteon size and shape over time are not fully understood and may be related to factors such as bone formation rates, activation frequency, and osteon population density. The material currently available for elucidating the specific relationship between osteon geometry and age is at a preliminary stage and significantly more research is needed.

Sex and Ancestry

While it has been documented that bone density and the rate of bone remodeling differ between the sexes and between individuals from different ancestral groups, there is no agreement among studies that these differences exist with measurable consistency. Many histological methods for age estimation have developed sex-specific and ancestry-specific equations (Thompson 1979; Cho et al. 2002), while others indicate no significant differences between groups (Stout and Paine 1992). Sex differences observed in histological variables are likely related to biological factors involving the endocrine system that affect bone turnover in the female skeleton, such as pregnancy, lactation, and menopause. Females experience bone loss associated with a drop in estrogen levels following menopause, which manifests in the loss of trabecular connectivity and increased porosity within the Haversian envelope of cortical bone. Biocultural factors (i.e., fecundity, breastfeeding practices, types of food consumed, or activity levels) may produce or extenuate histological differences between males and females that significantly impact bone biology. For example, a division of labor between sexes in a population may produce higher activity levels in one sex, causing bone to respond differently to the mechanical stresses and resulting in a perceived sex difference.

Histological differences observed between ancestral groups may be attributed to the population variability in cortical bone mass and density. Differences in skeletal growth velocity and duration will result in differences in bone mass and density. African-Americans, compared to European-Americans, have a slower bone turnover rate and a higher subperiosteal apposition rate resulting in greater bone volume (Cho et al. 2002). While differences in hormone levels that govern growth and development vary between populations, cultural aspects should also be considered when evaluating population variation at the histological level. Socioeconomic status may produce differences in activity levels, diet, and overall health, which may manifest at the histological level in bone.

Considering that histological methods produce conflicting results regarding sex and ancestry, it is also possible that some perceived group differences are an artifact of small sample sizes, skewed

sample distributions, or differences in histological sampling location. Therefore, caution should be followed when interpreting histological variables and results. Overall, population variation in bone histology likely reflects biological, genetic, and cultural factors.

Physical Activity

Biomechanical strain levels may vary depending on patterns of physical activity, which may be attributed to sex or ancestral group differences. Bone, being a dynamic tissue, will respond to biomechanical forces, or lack of forces, by altering bone resorption and formation rates (Inque et al. 2000). All bones receive biomechanical loading, including non-weight-bearing elements. Through histological analysis one may evaluate the microstructural changes caused by this biomechanical loading. A difficulty in anthropological studies is interpreting the load history where strain data are lacking or insufficient (Skedros 2011). The evaluation of mechanical loading in bone provides an understanding of bone adaptation within the lifetime of an individual in that bone structure and/or material organization will change in response to certain loading conditions (including reduction of loading as seen in disuse osteoporosis). The effects of stress/strain on bone are varied; however, bone must remain mechanically stable to reduce fracture risk. Biomechanical loading resulting from physical activity, assuming that the loading conditions are outside the normal physiological stress/strain range, provides stimuli that can accelerate intracortical bone remodeling. Studies from archaeologically derived contexts suggest the effect of habitual behaviors on bone results in both changes in gross geometry and intracortical bone remodeling. Therefore, one must consider that subsistence patterns and activity patterns vary between populations over geography and time.

Considerable research suggests that variation in the size and shape of osteons is linked to the biomechanical loading of bones. The analysis of this variation may be helpful in interpreting the load history of past and present populations; however, the challenge is in differentiating load history from other biological variables. While a well-substantiated framework for interpreting load history remains to be developed, Skedros (2011) introduced a worksheet/checklist of considerations to facilitate the interpretation in limb-bone diaphyses and ribs. Further work is needed to establish the control mechanisms determining osteon shape and size.

Pathological Conditions

Pathological conditions in skeletal remains can be often classified into particular disease groups through histological analysis. The interpretation of morphological structures at the histological level in archaeologically derived bone is particularly difficult due to postmortem changes and the maceration process, when compared to the information available from fresh tissue samples. Identifying pathological conditions in bone provides the basis for reconstructing the etiology and epidemiology of disease in past populations (Schultz 2001).

In the forensic context, the evaluation of pathological conditions in bone may assist with the determination of the cause of death. Of particular interest to forensic pathologists is identifying pathological conditions that increase the fracture risk of bone. Two conditions commonly explored that result in abnormally brittle bones are *osteogenesis imperfecta* and osteoporosis. In addition, metabolic conditions, dietary deficiencies, or other pathological conditions often lead to abnormal secondary osteon counts, which if used for histological age estimation, will produce inaccurate results. When evaluating bone for potential pathological conditions, it is important to consider the role of diagenesis and the impact of taphonomic factors that may mimic the histomorphology of diseased bone (Schultz 2001). Diagenesis refers to post-depositional changes that may affect both the chemical and structural integrity of the bone caused by taphonomic agents, such as water intrusion, bacteria, and fungi (Jans et al. 2004). Failure to recognize diagenetic agents may affect the reliability of histological analyses.

Conclusions

Skeletal remains are a storehouse of information regarding the biological processes experienced during the life of the individual. The use of histological methods in anthropology can strengthen other analytical results and provide information that cannot be obtained from gross methods alone. Through the qualitative evaluation of histomorphology and quantification of bone remodeling through histomorphometry, anthropologists are able to develop techniques to estimate age at death, evaluate load history, and assess skeletal health, contributing to the comprehensive understanding of skeletal biology.

Bones: Preservation and Conservation

Anne Rapp Py-Daniel
Universidade Federal do Oeste do Pará, Santarém, Pará, Brazil

Introduction

This entry discusses the conservation of a common archaeological remain: bones or, more specifically, bony elements. Our main purpose is to consider bony elements, common to all vertebrate, human and animal, from archaeological contexts and their final destinations in museums and laboratories.

Definition

What Is a Bone?

The bone is made of two main elements: organic (collagen protein) and mineral (hydroxyapatite $Ca_{10}(PO_4)_6(OH)_2$). These elements have very different functions and properties that in combination allow the bone to be at the same time hard and flexible, and as such it is an excellent raw material for several archaeological artifacts (White and Folkens 2000), such as Amazonian flutes, Paleolithic and Neolithic needles, and Paleolithic sculptures.

In a body, bones serve to protect and support soft tissues, to produce blood cells, as a storage facility for fat, and as a reservoir of calcium. Bony elements vary in size and shape according to the species and the individuals, but these are normally also related to sex and, in the case of fauna, domestication. Living bone is constantly transforming; it can repair and reshape itself depending on the type of stress it is put under.

The proportion of mineral and organic parts in bony materials depends on the function of the structure: bones, teeth, tusks, antlers, and shells all have different functions, and therefore the compositions and forms can differ quite a bit, for example, teeth have more mineral parts than the bone, shafts are hollow, while tusks are dense and compact, etc. The composition of bony elements affects the way these structures can be manipulated and has implications on their reactions to taphonomic processes following deposition (and after being excavated!).

Key Issues/Current Debates/Future Directions/Examples

Taphonomic Processes: "What Damages Buried Bony Elements?" and "What Can Preserve Bony Elements?"

The word taphonomy entered the academic record in 1940 when the Russian researcher Yefremov applied it to define "the study of the laws of burial" in paleontological contexts. Eventually its meaning was extended to the study of fossilization processes and paleoecological biases resulting from the passage of a body (human or animal) from a living community to a fossil one and from the environment where the body was buried (Behrensmeyer 1978). In these past decades, the term taphonomy is being used by many archaeologists as synonym for "the study of conservation and degradation processes."

Even though bony elements have a very significant percentage of mineral components – giving a false impression of being a stonelike material – there are numerous processes that can damage the structure of bones, be it mammal, reptilian, avian, or fish:

1. Decomposition: The bacteria responsible for soft tissue decomposition can also "attack" the organic part of the bones.
2. Environment: Exposition to weather conditions, rain, sun, wind, snow, and temperature can cause cracking and breaking.
3. Burial and transportation: A rapid burial is an essential element for conservation; long-term transportation can physically destroy bones completely.
4. Soil characteristics: Acidity, mineral composition, and granulometry (clay, sand, or silt) all affect preservation. In fine sands, the surface of

bones can become coarse with time, while in clay, soil "attaches" itself to the bone, being difficult to separate – some cleaning procedures might even damage the bones if the sediment is too attached.

5. Pre-depositional treatment: Human and animal bones frequently undergo some kind of treatment prior to being buried or discarded. One should expect treatments that vary from defleshing to cremation, boiling, painting, etc. All of these activities have impacts on preservation. For instance, burnt bones survive quite well but are normally highly fragmented, while teeth usually "explode" into micro-unidentifiable fragments when burnt. Mummification processes, be they natural or artificial, can help preserve not just bones but also soft tissue and keratin elements (like hairs and nails); nevertheless a mummified body can decompose if the environmental conditions change.

Most bones found in archaeological sites are in fact decomposing not fossilizing; the site's environment affects the rate of this process. For instances, in tropical areas, where the soil is normally very acidic, the weather conditions are quite rough (temperature and humidity are high), and microbiological activity is extremely intense, bones sometimes do not preserve beyond a few hundred years (or less), and when they are recovered, the deterioration is so advanced that it renders identification and other analyses (like dating) difficult or impossible. Meanwhile in Europe, where the soils are neutral or slightly basic, it is quite normal to find non-fossilized bone in archaeological sites thousands of years old. Some kind of equilibrium is needed in order for long-term preservation to exist.

It is important to note that finding preserved bone does not mean finding fossils. Fossils are bones or teeth that no longer have organic parts, because they have been replaced by mineral elements in contact with the soil.

What Can We Learn from Bony Materials?

The study of bony materials can provide information about a range of archaeological questions, and these applications justify the long-term storage of bone (Lyman and Fox 1997):

1. Differentiating human from animal contexts (see Figs. 1 and 2)
2. Estimating minimum individual number, sex, age, stature, and health
3. Domestication processes for animals
4. Cultural materials and artifacts
5. Feeding habits
6. Disposal habits
7. Environment
8. Population patterns
9. Funerary practices
10. Death patterns (isolated, catastrophic, etc.)

How to Preserve Bony Elements?

Unfortunately, few museums around the world have the proper means to care for all their archaeological artifacts. Yet, simple and practical actions do exist and can help preserve bony elements for long periods of time. To conserve such artifacts correctly, one must understand:

1. The conditions where the elements were found. Changing the environment too abruptly and permanently usually leads to deterioration of the organic parts and sometimes to total destruction.
2. The bony elements conditions at the moment of their retrieval. If the conservation conditions at the field are precarious, it may be necessary to apply stabilizing agents, in order to remove, finish the excavation, and follow cleaning procedures, if necessary, in the laboratory.
3. The final destination: Most organic materials react rather badly to environment variation. So, in order to preserve these elements, there must be continuity! This means understanding and controlling the environment at the final destination.

Collagen (organic part) in the bony elements reacts to the removal from the soil by drying and shrinking or by moistening and swelling; in both cases, this leads to cracking of the bone's surface and, sometimes, inner structures.

"When," "How," and "Why" to Clean Bones Are Dependent on the Conditions in Which the Bony Elements Were Found and the Projected Analyses

Before starting the cleaning procedures, it is necessary to make a thorough evaluation of the bony element, noting how preserved or damaged it is. Dry and wet materials react differently once taken from dry soil or flooded areas, and the preventive actions (glues, consolidants) that might have been needed may subsequently interfere with the cleaning procedures. Another important factor to be taken into consideration is that bones (human and animals) are often remodelled into artifacts or transformed by pre-depositional treatments; therefore, cleaning should not "erase" or "remove" these traces, when possible X-rays can assist in this process of evaluation.

Differently from other more robust archaeological remains, like stone and some ceramics, washing with abundant water and brushes can damage bony elements by removing the superficial layers or causing them to crack and eventually break into small fragments. Therefore, many archaeologists are experimenting dry-cleaning their materials with scalpels and using controlled solvents in specific areas. Scalpels are delicate to use because they are very sharp and therefore dangerous, but usually it is easier to clean with a scalpel. Even hard and attached clay soils can be removed without much effort, and if by misfortune, the archaeologist "carves" the bone, it leaves a very distinctive mark, easily differentiated from prehistoric artifacts. Wooden utensils demand the application of more strength during cleaning procedures and can eventually cause the bone to shatter, but it is still a very good utensil. Solvents are good for removing incrustations that cannot be cleaned mechanically, but they must be used carefully because in large amounts, they can erode the bone's surface.

Bony elements that are found in wet/damp conditions are best cleaned before the surrounding soil dries out completely. As we mentioned before, this process must be done slowly and carefully; abrupt changes in the micro-context of the bones can cause damages. Once dried, bones should not be remoistened.

Issues of Long-Term Storage

Like in all scientific work, in archaeology, one should leave part of the material studied for future analyses: thinking of future researchers who might create better techniques or have different opinions.

Conducting archaeological excavations implies recovering old materials that need to be

Bones: Preservation and Conservation, Fig. 3 An example of storage procedures: human bones being stored in polypropylene material. (Photo by A. Rapp Py-Daniel)

cared for a very long time. Appropriate storage areas are a problem for archaeologists and museums all around the world. The need for space is forcing some archaeologists to rethink their fieldwork plans and to choose smaller expeditions where fewer materials are recovered.

Scientific collections demand special care. Most recovered bones were in a slow (or not so slow) process of decomposition, and this needs to be taken into account when planning excavations and long-term storage. Remembering that all organic materials should only be stored once they are completely stabilized, one must first think of the bone's condition and which materials will be in direct contact with the bony elements (see Fig. 3).

As Cronyn (2004) states, stabilization can either be passive or active – unfortunately, most laboratories only have the first option. A passive stabilization involves controlling the "new" environment and allowing the bony materials to dry (or keeping them wet) until they achieve an equilibrium. The density of the bony materials (bones, ivory, etc.) will also have an impact on the time it will take for stabilization to occur. When bony materials have to go through an abrupt change in the environment, like the removal from wet conditions, the application of a chemical product (Cronyn 2004) to consolidate and "force" stability is usually needed – the most frequently used are PVAC and polyethylene glycol.

Once the archaeological remains are stabilized, storage considerations should include appropriate conditions:

- Bony materials should be in direct contact with "soft" materials, like plastic bags or preferably bags made of polypropylene, that are neutral and not toxic.
- Storage should not be in paper bags or cardboard boxes that decompose rapidly and attract animals like termite and ants.
- The integrity of the bony material is a key element; when cracking and breaking are observed, it is valuable to consider storage in areas where there is little handling.
- Cracking bones should not be kept in direct contact with each other.
- Large and heavy bones should not be stored with small fragments or teeth.
- Common sense is always the best policy.

Basic Biographical Information

Born in Venice, Italy, on April 25, 1859, Giacomo Boni was a prominent figure in the development of the discipline of Roman archaeology and, in particular, a key figure in the excavation of contexts connected to early Rome. Boni studied architecture in Venice and worked there as an architect but is best known for his excavations at Rome, especially those in and around the Forum Romanum undertaken from 1898 onward. He saw military service in World War I and resumed his fieldwork in 1916. He was appointed as a member of the Italian senate in 1923 and died in Rome, Italy, on July 10, 1925, and is interred in the Orti Farnesiani on the Palatine Hill.

Major Accomplishments

Boni's excavations in Rome resulted in many significant archaeological discoveries, and it is for this work that he is most well-known; in fact, Boni was a pioneer in terms of excavation methodology. Boni's stratigraphic excavations in the center of Rome were revolutionary, as no one had ever undertaken deep soundings at Rome that followed stratigraphic principles before (Ammerman 1990: 630). Indeed, Boni's stratigraphic excavation was one of the first of its kind in the field of Classical archaeology. Beginning in 1903, Boni's excavation reached a depth of more than 6 m, taking him below the modern water table, an excavation in which his early experience as an architect working in Venice proved useful. In the deep soundings at the center of the Forum Romanum, Boni would document more than 30 anthropic strata that told the story of the artificial landfill project undertaken in the archaic period to raise the ground level of the Forum itself. These layers, and Boni's work, would be returned to in the middle of the twentieth century by Swedish archaeologist Einar Gjerstad.

Boni's excavations also revealed important finds in and around the area of the Forum Romanum. These included the Iron Age necropolis near the Imperial temple of Antoninus Pius and Faustina known as the *Sepolcretum* (1902), the *Lapis Niger* (1899–1905), and the *Regia*, as well as sites on the slope of the Palatine Hill including the House of the Griffins. Despite interrupting his work to serve in World War I, Boni returned to digging at Rome and continued to work there until the end of his life.

Borrero, Luis A.

Karen B. Borrazzo
Instituto Multidisciplinario de Historia y Ciencias Humanas, CONICET, Buenos Aires, Argentina
Universidad de Buenos Aires, Facultad de Filosofía y Letras, Departamento de Ciencias Antropológicas, Buenos Aires, Argentina

Basic Biographical Information

Luis Alberto Borrero is an Argentine archaeologist, born in the Patagonian city of Río Gallegos and raised in Azul (Buenos Aires Province). He completed his undergraduate studies in anthropology in 1978 and received his Ph.D. in 1986. Both studies were undertaken at the University of Buenos Aires, where Borrero has held a professorship since 1986. Luis Borrero has been a Research Fellow for the National Research Council of Argentina (CONICET) since 1983.

After receiving his Ph.D., Borrero was awarded several scholarships and grants to complete specialized training programs abroad, many of them pertaining to methodological issues including taphonomic analysis, formation processes, ethnoarchaeological research, and dating techniques in archaeology (1980–1991) (Borrero and Yacobaccio 1989).

In the late 1980s, Luis Borrero started the Magallania Archaeological Project, focusing research attention on regions north and south of the Magellan Strait (Fuego-Patagonia, southern South America) (Borrero 1991).

Major Accomplishments

Luis Borrero's research is centered on Patagonian hunter-gatherers, with particular emphasis on theoretical and methodological issues in hunter-gatherer archaeology, Pleistocene megafaunal extinctions, and the initial peopling of southern South America. Since the very beginning of his career, Borrero has made significant contributions to the discipline, including theoretical models, actualistic data, and insightful analyses of the archaeological record.

While finishing his doctoral dissertation, Borrero began his research on taphonomy, which initially included longitudinal studies of guanaco (*Lama guanicoe*) remains in Tierra del Fuego, and later incorporated similar studies of several other mammalian taxa (Borrero 1990, 2007). His pioneering work in taphonomy as well as his early research on formation processes in archaeology promoted a methodological transformation in Argentine archaeology (Gutierrez et al. 2007).

By integrating taphonomy, geoarchaeology, and distributional archaeology, Borrero proposed a "regional taphonomy" approach, which has been the framework for his intensive fieldwork, predominantly in Argentine and Chilean Patagonia (Borrero 2001a, b). Borrero's research on Pleistocene megafaunal extinctions in South America is primarily based on his own fieldwork

in Última Esperanza, Chile. Borrero has published comprehensive assessments of the respective roles of human exploitation and climate change in South American faunal extinctions during the Pleistocene-Holocene transition (Borrero 1997, 1999a, 2008; Borrero and Martin 2012).

Borrero's contribution to our understanding of the peopling of southern South America (Borrero 1994–1995, 1996, 1999b, 2006, 2011) includes a three-stage model (exploration, colonization, and effective occupation), which details material expectations for archaeological records of the peopling of previously unoccupied areas. This model is currently a major framework for Patagonia research and has been shown to be applicable elsewhere.

Luis Alberto Borrero has received numerous awards for his contributions to the discipline of archaeology, including the *Bernardo Houssay's Award to Scientific and Technological Research* (Argentina 2004) and the Award for Excellence in Latin American and Caribbean Archaeology of the Society for American Archaeology (USA 2014). He has trained a large number of practicing archaeologists, producing a deep and lasting influence on Argentine archaeology.

Bowdler, Sandra E.

Jane Balme
Archaeology, University of Western Australia, Crawley, WA, Australia

Basic Biographical Information

Sandra Bowdler is now Emeritus Professor in Archaeology at the University of Western Australia. She grew up in Sydney, Australia, and obtained a first class honors degree with university medal in Anthropology from the University of Sydney in 1971. She then worked as a tutor at the University of Papua New Guinea before going on to undertake, and in 1979 complete, a PhD in the Research School of Pacific Studies at the Australian National University on aspects of archaeology of Hunter Island, Tasmania. Toward the end of her Ph.D., she took up a lecturing post at the University of New England where she stayed for 4 years before working as a consultant archaeologist particularly to the Forestry Commission of New South Wales. In 1983, Sandra Bowdler was appointed as foundation chair in archaeology at the University of Western Australia. This appointment so early in her professional life is a testament to the contribution that she had made to the discipline so early in her career. Professor Bowdler continued in that position until her retirement in 2008.

Major Accomplishments

In the course of her archaeological career, Sandra Bowdler's research has spanned a diversity of themes, theoretical concerns, and geographic areas, although her interest has been primarily in the Australasia and Southeast Asia regions. Sandra's early research on coastal midden sites in New South Wales was particularly concerned with the way in which Aboriginal people had organized themselves. In writing up her first professional excavations of these middens, Sandra attempted a new type of midden study that was both testable, in line with the then "New Archaeology," and the same time was "about people." Social groups, especially women, had been invisible in Australian archaeological writings and Bowdler (1976) remains one of the few pieces of research in Australia that has exploited the potential of using gender as an analytical category. Her interest in the way in which gender is constructed in the past has continued throughout her career. Sandra's early research on coastal middens expanded to include an interest in all aspects of coastal archaeology but particularly the unique conditions imposed for colonization (e.g., Bowdler 1977, 2010), Tasmania (e.g., Bowdler 1984a), and the use of small offshore islands (e.g., Bowdler 1995).

Sandra brought a new level of professionalism to consulting archaeology in Australia during her brief period as a consultant in the 1980s. Consultancy in Australia has expanded exponentially, and Sandra's challenging contributions on significance assessment (e.g., Bowdler 1984b) and the imperative to make consultancies relevant to timely research questions remain as important today as they were at the time of publication.

Working as a consultant meant that Sandra also had to confront the many of grievances of Indigenous peoples in the heritage process and in archaeological practice generally. Questioning the objectivity of concepts of "significance" and whether or not scientific objectivity was possible in a heritage framework were big issues for archaeologists at the time. Sandra advocated the primacy of Indigenous interests in archaeology. When the

rights of Indigenous people to repaint their sites was questioned by some academics and rock art practitioners following the 1987 Ngaringin Cultural Continuity Project, Sandra took a strong ethical stand arguing that Indigenous rights should take precedence over non-Indigenous national heritage agendas and urging those critical of the repainting project to "ask themselves what is more important, the preservation of a few relics of the recent past, or the active continuation of that living culture?" (Bowdler 1988: 523).

In the 1990s, Sandra became increasingly interested in the Southeast Asian region, in the colonization of Sunda and Sahul by modern humans, and in comparisons between the material cultures of the two regions. This led to comparative studies of Pleistocene stone industries from Australia and Southeast Asia and her interest in the Hoabinhian culture complex (e.g., Bowdler 2006).

Despite her retirement, Sandra continues her interest in archaeology and, since 2015, she has been the chief editor of *Australian Archaeology,* the journal of the Australian Archaeological Association. Her other main interest is music, especially baroque music, and she contributes reviews to a variety of opera magazines and online forums.

Bradshaw (Gwion) Figures: Initial Observations Drysdale River, Kimberley 1986/88

Joc Schmiechen
School of Humanities and Creative Arts (Archaeology), Flinders University, Adelaide, SA, Australia

State of Knowledge and Current Debates

The Region

The Drysdale River is one of the largest rivers in the Kimberley region of north-west Australia. It rises near Mt Hann and flows north some 400 kilometers to Napier Broome Bay in the Timor Sea (McGregor and Chester 1992) (Fig. 1). It was first

Bradshaw (Gwion) Figures: Initial Observations Drysdale River, Kimberley 1986/88, Fig. 1 North East Kimberley region showing Drysdale River, Drysdale River National Park. (Rainsbury 2009)

made known to Europeans in 1886 by Charles Burrows who came upon the river while seeking pastoral lands for the Victorian Squatting Company (Schmiechen 1992; Rainsbury 2009). The river valley covers 16 000 square kilometers – with a permanent population of around ten people – mainly cattle station owners, managers and employees. The country the river flows through is isolated, diverse, and for large sections extremely rugged, impassable to vehicles, and difficult on horseback. Like the other major Kimberley rivers, it is subject to massive fluctuations in water flow driven by the annual wet season monsoons. During the "wet" from November to April, up to 1400 millimeters of rain falls in the catchment (Kabay and Burbidge 1977), turning a placid string of waterholes into a raging torrent, in places 2 kilometers wide. In the winter months of the "dry," the river virtually disappears into huge sandy beds and boulder-choked gorges. Only a series of waterholes and deep *Pandanus*-fringed reaches remain.

The terrain cut by the river varies immensely. Near its headwaters the river meanders across a broad, gently undulating plateau. White barked gums and spiky *Pandanus* line the river, and the surrounding plains are covered with savannah woodlands. In the lower reaches, the country changes dramatically. The landscape is deeply eroded into tortuous gullies and strangely shaped rock outcrops. Stately gums give way to stunted eucalypts, acacias, and paperbarks, and the air is thick with the cloying scent of *Spinifex*. The river twists its way through ever steepening, boulder-strewn gorges. Ochre-colored terraced cliffs dominate the skyline. This is a particularly rich and

diverse environment with much wildlife and plant foods. As such it provided a sheltered and food-rich territory for an extended period of occupation by the early Aboriginal inhabitants.

The nearest major population center is the Aboriginal community at Kalumburu, located on the King Edward River west of the Drysdale River mouth. Originally founded as a catholic mission by Benedictine monks from Spain, it became a gathering point for the various tribal groups who traditionally occupied the surrounding lands (Perez 1977).

The Operation Raleigh Expedition

In May 1986 an international expedition under the auspices of Operation Raleigh and led by Clive Richardson completed the first successful descent of a major section of the Drysdale River. From its starting point at Drysdale River Station, the expedition travelled some 320 kilometers to Napier Broome Bay (Richardson 1986) (Fig. 2). At the time of the expedition, no Europeans were known to have travelled the length of this major river. I was fortunate to accompany the expedition as scientific leader with one of my main responsibilities to record Aboriginal cultural heritage discovered along the way, especially rock art. The expectation was that examples of the well-known Wandjina figures would be found. These dramatic paintings of ancestral Dreaming beings had been of great interest to missionaries Ernest Worms (1955) and James Love (1917, 1936) and later to anthropologists Adolphus Elkin (1930), Charles Mountford (1937), and members of the German Frobenius.

German Frobenius Expeditions (1938–1939). In the 1960s Ian Crawford, Curator of Anthropology and Archaeology at the Western Australian Museum, was taken to some of the great Wandjina sites by Traditional Owners. He published his findings in a 1968 book, *The Art of the Wandjina*. I had studied his book meticulously and expected to find many examples of Wandjina art on our river descent.

The river journey proved extremely challenging for many of the young international expeditioners, with rapidly falling water levels necessitating long days of hard paddling to avoid possible lengthy portages. For much of the middle part of our decent, we passed through the Drysdale River National Park. This park was gazetted as a Class B reserve in 1973 and upgraded to a Class A reserve in 1974 (Kabay and Burbidge 1977). It is one of the most remote and least-accessible parks in the Kimberley, with limited vehicle access. The Drysdale River traverses the length of the park for some 80 kilometers. Many key locations in the park were named by Kabay and Burbidge during a 2-week biological survey carried out in 1975.

It was while navigating the twisting gorge below Solea Falls that an abundance of Aboriginal rock art was discovered on nearby rock walls and overhangs (Schmiechen 1986). This was not the expected Wandjina art but consisted almost entirely of the pre-Wandjina styles then collectively referred to as Bradshaw art. Among the figures found were many examples of what were referred to by Crawford (1977) as "Classic Bradshaws" – generally monochrome red, elegant, naturalistic human figures, heavily adorned with ceremonial accoutrements and carrying boomerangs. As consecutive Drysdale galleries were found, I recognized five distinct types of Bradshaws. In 1988 I returned to the Drysdale River with a small team and began a systematic exploration and recording program of what has turned out to be one of the most concentrated bodies of Bradshaw art in the northern Kimberley (Schmiechen 1993; Veth et al. 2018). Later that year at the first Australian Rock Art Research Association (AURA) Congress in Darwin, I presented a paper that provided a historical background to rock art research on the Drysdale, with an account of my 1986 and 1988 fieldwork, and a preliminary stylistic analysis of the art. To help fill out the history of rock art research on the Drysdale River, an edited version of that paper is presented here for the first time.

Background to Kimberley Rock Art Research

In the late 1830s, George Grey undertook several exploratory expeditions in the Kimberley and

Bradshaw (Gwion) Figures: Initial Observations Drysdale River, Kimberley 1986/88, Fig. 2 Drysdale River National Park. (Welch 2016)

recorded some of the first impressions of Aboriginal rock art along the Glenelg River. The paintings he found were some of the now famous Wandjina figures (Grey 1841). Some 50 years later, while surveying the pastoral potential of land near the Prince Regent River, Joseph Bradshaw recorded the first European observation of a very different style of Kimberley rock art. Bradshaw (1892) described his find in the following way:

We saw numerous caves and recesses in the rocks the walls of which were adorned with native paintings, coloured in red, black, brown, yellow, white and pale blue. Some of the human figures were life size, the bodies and limbs were attenuated, and represented as having numerous tassel shaped adornments appended to the hair, neck, waist, arms and legs, but the most remarkable fact in connection with these drawings is that wherever a profile face is shown the features are of a most pronounced aquiline type, quite different from

> those of any natives we encountered. lndeed, looking at some of the groups one might almost think him viewing the painted walls of an ancient Egyptian temple. These sketches seem to be of great age, but over the surface of some of them were drawn in fresher colours, smaller and more recent scenes, and rude forms of animals, such as the Kangaroo, Wallaby, Porcupine, Crocodile, etc.

Little additional information about these mysterious figures was forthcoming for many decades.

The establishment in 1908 of the Drysdale River Mission at Pago, not far from the Drysdale River mouth, provided the first permanent European settlement in the region and a base from which later explorers and researchers could examine the surrounding country (Perez 1977; McGregor and Chester 1999; Walsh 2000). During his extensive survey of the Kimberley in 1901, Frederick Brockman followed much of the lower Drysdale, and the naturalist on the expedition, F.M. House, photographed several Wandjina sites they found on their travels. Most of his comments related to the now well-known Wandjina figures. In 1910, entomologist Gerald Hill sketched a number of rock paintings around Napier Broome Bay near the Pago Mission (Walsh 2000; Donaldson 2012; Rainsbury 2017). Among them were a number of small red anthropomorphic figures in a variety of action poses. C.P. Mountford, in a paper published by the Royal Society of South Australia in 1937, offered an interpretation of these figures and compared them with Bradshaw's sketches. Mountford had seen a significant array of Aboriginal art across Australia and made the comment that one of the Napier Broome Bay figures represented "one of the finest examples of Aboriginal art in which action is portrayed."

C. Price Conigrave was in the Kimberley in 1911 on a private expedition, primarily to make a botanical collection. He visited the lower Drysdale and tried to follow it south but was blocked by the river gorge near Solea Falls (Conigrave 1938; Rainsbury 2016). He reported the discovery of ground images – human and animal silhouettes made on the flat ground surface by clearing the internal parts of the image. He also reported a series of rock art sites but provided no details about them.

In 1927–1928 anthropologist A.P. Elkin conducted fieldwork near Walcott Inlet on the west Kimberley coast, studying the Wandjina rock art of the region. On seeing some strange profile figures, he commented that they were not typically Aboriginal and were similar to the paintings described by Bradshaw. Unfortunately, he never elaborated on his observations in any subsequent publication.

In 1938 the German Frobenius-Expedition undertook a major scientific survey of the then little-known body of Kimberley rock art and its associated culture. Their main focus was the visually dominant Wandjina art, although they did acknowledge a stylistically distinctive and different art body. Agnes Schulz, one of the expedition's artists, published an account of their findings in 1956. She described a number of faded human figures which she named "Bradshaw paintings," due to their apparent similarity to Joseph Bradshaw's original finds. From then on the connotation "Bradshaw paintings" loosely encompassed a wide range of styles of mainly small red figures that predated Wandjina art. The Frobenius Expedition learnt that local Aborigines considered these "Bradshaw" figures as being of great antiquity and well outside the current mythological context. The Aborigines claimed no cultural relationship to these paintings and generally disregarded their existence. Other recorders observed similar responses denying any association with the Bradshaw art (Worms 1955; Crawford 1968; Walsh 1994, 2000).

Pallottine missionary Father Ernest Worms was another early recorder of anthropological data in the Kimberley. In 1953–1954 he made several expeditions from Broome into the central and far northern portions of the region, specifically to search for these small red figures (Worms 1955). He discovered numerous examples and claimed to have found some portraying action more realistically than the one Mountford had described so enthusiastically. Worms described their characteristic chocolate-brownish shade and the extreme finesse of their execution, especially when compared to the much more crudely

executed Wandjina art. Worms also observed that the pigment of the small red figures seemed to have fused so completely with the underlying sandstone that they resisted all attempts to scrub it off. He noted that his Aboriginal companions and guides did not show the slightest interest in this type of art which they stated were the products of another people, long before their time. They told him that both the paintings and the painters were called "Giro Giro." Worms commented on the similarity of his finds with those of Hill, and based on their faded and deteriorated appearance and on the comments of his guides, he was convinced of their great age.

Dr Andreas Lommel, a German anthropologist and member of the 1938 Frobenius Expedition, was intrigued by these paintings and in 1954–1955 returned to the Kimberley to follow up on his earlier work (Lommel and Lommel 1959). He made numerous discoveries of the then designated "Bradshaw style" figures, often in conjunction with Wandjina sites. In his subsequent publication, *Die Kunst des fünften Erdteils*, he called these figures "the elegant style," a most apt description for the more exquisite Classic Bradshaw figures.

In the mid-1900s a number of pastoral leases were established on the western side of the Drysdale, but little exploration activity was carried out along the river's course due to the inaccessibility of the terrain. In the 1960s and 1970s, further attempts at evaluating Bradshaw art were made by Ian Crawford, Curator of Anthropology and Archaeology Western Australian Museum (Crawford 1968, 1977), and also by Melbourne-based professional photographer Dacre Stubbs (1974, 1981). Both postulated a number of ideas on the evolution and possible origin of the art. Crawford drew on his own work and the findings of previous observers, particularly Lommel and Lommel (1959), to define the main features of the "Bradshaw style." His definition (Crawford, 1977) encompassed the following characteristics:

1. Human figures with distinctive body features – muscles, shoulders, and stomachs accentuated, sometimes facial profiles clearly and carefully depicted with curvaceous delineation.
2. Small – usually around 30 cm but up to 130 cm.
3. Predominantly red in color – some evidence that they may have included other colors.
4. Implements shown mainly boomerangs and barbed spears.
5. Nearly always shown in vertical aspects (standing, dancing, running).
6. Usually in group arrangements in action sequences. Some individuals may be single relics.
7. Exhibit use of a very fine painting technique use of fine brushes.
8. Widely distributed – often in poor state of preservation and found in all manner of sites from large galleries to isolated boulders.
9. The classic form of these figures is quite distinct from other figures, with some similarities. Possibly some of these are contemporaneous.

Crawford suggested that the barbed spears associated with these figures were a possible indication of age. In the art this type of spearhead was superseded by depictions of what appeared to be leaf-shaped stone spearheads. Spearheads of this type first appear in Kimberley archaeological deposits some 3000 years ago (Crawford 1968).

Dacre Stubbs, author of *Prehistoric Art of Australia* (1974), had a long fascination with Bradshaw art and spent considerable time and effort on many field trips to collect information, culminating in an unpublished manuscript, *Kimberley Mystery Paintings*, written in 1980. In many of his findings he concurs with the observations of Crawford. Additional features noted by Stubbs included the lack of a clear indication of gender typical of much other Aboriginal art (Worms also noted this) and the depiction of elaborate decoration and ornamentation, including many types of headdress, skirts, bags, armlets, wristlets, anklets, scarf-like arrangements, and implements like batons, fans, and fronds. Stubbs further noted that Classic Bradshaw figures were mostly filled-in silhouettes with very few outline figures and that a nonaggressive mode prevailed among the representations. He believed most figures were shown in dancing and ceremonial poses, often with a characteristic bent knee action.

The Kimberley Foundation Australia (KFA) was formed in 2002 as a philanthropic

organization to encourage scientific research of Kimberley Aboriginal rock art, in conjunction with the Traditional Owners, as a means to preserve and promote its national and international significance. In recent years KFA has been instrumental in obtaining funding for a number of major research projects, including two Australian Research Council (ARC) linkage grants for projects that are at the forefront of current academic research, utilizing much of the data from the extensive surveys undertaken in the Drysdale and King George River regions since 1988.

Bradshaw Art: Changing Nomenclature

As mentioned earlier, the name "Bradshaw art" or "Bradshaw figures" was first used by Agnes Schulz of the Frobenius Expedition, in reference to explorer and pastoralist Joseph Bradshaw who had first described these figures and in the apparent absence of a clear Aboriginal name (Schulz 1956). However, the various Aboriginal groups in the north Kimberley do have their own names for these paintings including Gwion Gwion, Kiera-Kirow, Kirakiarn, and Giro Giro (Walsh 1988, 2000; Welch 1990, 1993a, 2015, 2016; Rainsbury 2010). The Ngarinyin term Gwion Gwion was the title of a book published in 2000 (Doring 2000) and is now the generally accepted name among academic researchers, though usually abbreviated to just "Gwion."

Not only has the original European term "Bradshaw" been largely replaced with "Gwion Gwion" or "Gwion," but in a 2012 publication, Donaldson applied local Wunambal names to the various styles of Bradshaw art identified by myself (1993), Walsh (1994, 2000), and Welch (1993a, b, 2015, 2016). Travers and Ross (2016) have followed this convention, recognizing the Wunambal Gaambera descriptors as published by Donaldson.

Crawford (1977) first used the term Classic Bradshaw to describe the ornamented, naturalistic human figures, curvaceously delineated and depicting clear body features, such as muscle and shoulders, stomachs, and sometimes facial profiles. On the 1986 Raleigh Expedition, I had identified two clear variants, distinguished mainly by their stance and material adornments. I initially designated them as types A and B and described them as such at the 1988 AURA conference. These were later referred to by Welch (1993a, b) as Tassel and Bent Knee Figures and by Walsh (1994, 2000) as Tasselled and Sash Bradshaws (Walsh 1994, 2000). In the course of my subsequent work and in this paper, I refer to them collectively as Classic Bradshaws and individually as Tassel and Bent Knee Bradshaws (Schmiechen 1993) (Fig. 3).

Lee Scott-Virtue and Dean Goodgame, long time Kimberley rock art researchers, take a completely different approach to the term Classic Bradshaw. They present a chronological sequence in which they identify four major stylistic periods in what they continue to refer to as "Bradshaw art." They also suggest a distribution pattern for the figures in each period. The earliest of their styles, Classic Bradshaws, they divide into Classic Realistic and Classic Abstract. The remaining periods are described as Complex Bradshaw, Stylised Bradshaw, and Simple Bradshaw (Scott-Virtue and Goodgame 2017).

At the time I wrote my 1988 paper, the term "Bradshaw" was not an issue with the local Traditional Owners and was still in general use among rock art researchers. Acceptance of the Ngarinyin name Gwion Gwion had not occurred. While acknowledging the appropriateness of adopting the terminology Aboriginal people use for their cultural heritage, as this paper largely reproduces my 1988 report, I have retained the term "Bradshaw." A lightly edited version of the section of my 1988 paper that describes the styles of rock paintings discovered on the Drysdale River is reproduced below.

Bradshaw Figures: Stylistic Variations and Similarities – Some Initial Conclusions Drawn from Two Expeditions to the Drysdale River Area in 1986 and 1988

The rock art discovered on the Drysdale River in 1986 and 1988 encompassed the whole spectrum

Bradshaw (Gwion) Figures: Initial Observations Drysdale River, Kimberley 1986/88, Fig. 3 (**a**, **b**) Classic Bradshaws. Type A Tassel Bradshaws and Type B Bent Knee Bradshaw, Drysdale River

of styles that had been ascribed within the Bradshaw classification. Initial analyses of these figures show a number of clearly identifiable styles with specific characteristics. Much of the art seen was in fair to good condition, with some examples seemingly as clear as the day they were painted. The bonding with the sandstone of the pigments used in the various styles of Bradshaw art has rendered them impervious to all but actual ablation of the rock. As described in 1988, these identified styles are outlined below.

Classic Bradshaws

By far the most visually striking were the many well-preserved examples of the so-called Classic Bradshaw style. These finely painted figures were notable for their sense of flowing movement and grace. In many cases they seem to float across the walls of the shelters, an impression accentuated by bent knees and downward pointing feet. Alasdair McGregor, a noted professional artist who accompanied the 1988 expedition, commented particularly on the fine brush work and marvelled at the exquisite detail of their execution (McGregor personal comment in the field, 1988). In almost every case, these figures are shown in profile and always appear as filled-in silhouettes, mainly in monochrome and ranging in color from a dark brown-black, like dried blood, to varying shades of mulberry hue, terracotta, and a bright-red-brick color which gives the appearance of very recent application. A relatively recent application is unlikely as there is little if any discernible pigmentation left, and only a shadowlike image remains on the rock face. Another distinguishing feature of the Classic Bradshaws is the extensive and varied ornamentation, apparel, headdresses, and hairstyles. Ornaments and accessories include shoulder tufts like epaulettes, flowing tasselled underarm ornaments, elbow tassels, wristlets, anklets, dilly bags including a distinctive kite like version, palm fronds, fanlike objects (possibly bird wings), batons, and multiple boomerangs. Spears appear only rarely with these figures and in the examples found they are all single-barbed.

Head ornamentation is varied and highly elaborate. Most common are different forms of cones. These included short upright cones (later dubbed "dunce caps" by Walsh 1994), commonly topped with a frond or a tassel. Some figures wore long sweeping cones, often of body length, topped with tufts or tassels. Some of them have feathers protruding backward from their base. One figure was

Bradshaw (Gwion) Figures: Initial Observations Drysdale River, Kimberley 1986/88, Fig 4 Bent Knee Bradshaw Winged Figure, Drysdale River

Bradshaw (Gwion) Figures: Initial Observations Drysdale River, Kimberley 1986/88, Fig 5 Classic Tassel Bradshaws – "ceremonial couple," Drysdale River

recorded with very clear and finely painted wings extending from the front of the headdress (Fig. 4). This was unusual and had not been noted in previous accounts. We designated this as the "Winged Figure." Only a small number of such figures has been recorded in subsequent surveys. Oval-shaped hairdos or head garments, commonly adorned with feathers, also occurred. Predominant was a long tied-back hair-bun, ending in a knot with feathers attached.

As great as the variety of headdresses was, so it was with apparel worn. This included a lap-lap type sash streaming out from the waist at the front and rear. Another common feature was a very distinct three-strand waist belt where each strand ended in a distinctive pom-pom with two or three tassels from its end. This was widespread among figures from this area and also among examples from other regions a considerable distance away. Other garments included fringed skirts, strand-like grass skirts, and full-length skirts. These were generally pinched in to accentuate the waist. Some figures wore boa-like objects, shown as a series of dotted lines. Very fine detail of physical features is shown in these figures, especially in the more elaborate examples. Leg and arm muscles are clearly defined, shoulders are high and accentuated, and bodies are shown as tall and slender with nipped in waists and commonly with a distinctive stomach bulge. In every aspect these features match Lommel's description of "elegant art" (Lommel and Lommel 1959).

Sexual features were not readily apparent and genitalia were never visible. It has been suggested that these figures represent only males in ceremonial attire. This viewpoint may have originated from the idea that in traditional society most ceremonial activity was a male domain. This assumes that the people who created the Bradshaw figures subscribed to similar traditions, but there is no evidence this was the case. Indeed, within some groups of figures, there are differences that could be taken to indicate both male and female figures.

An example here is (Fig. 5) a pair of exquisitely ornamented figures, both with similar

tied-back hairstyles adorned with feathers and wearing scarf-like arrangements. One figure is larger than the other and there are some notable differences in apparel. The larger figure has the three-strand waist appendage with the characteristic pronged tassels extending from one end. The smaller figure has a skirt pinched in at the waist and reaching to mid-thigh. The size differential and the difference in dress raise the possibility that the figures represent a man and a woman in ceremonial attire.

The three-pronged waist appendage with its distinct end tassels may well have been a feature of male dress, while the flowing skirts and dress-like garments may have been worn by women. In nearly all cases, the figures shown with weapons such as spears and boomerangs wear the tassel belt or sash style garment. These are only initial conclusions, and more careful analyses should help to establish or refute these patterns. At this time we can only speculate on the meaning of what is depicted, and it would be a mistake to assert that the figures shown represent only males.

Many of the characteristics discussed so far agree in essence with observations and conclusions made by Worms, Lommel, Crawford, and Stubbs. There are, however, additional features among the Drysdale figures which add to and alter some of the previous perceptions. The size range ascribed to Bradshaw figures has generally been that of miniatures from 30 to 130 centimeters (Crawford 1977). Bradshaw described his finds as being life size, yet this seems to be uncommon with most examples recorded being more in the miniature category. Common size on the Drysdale was 8 to 80 centimeters. A number of life-size figures were found on the Drysdale, the largest being 165 centimeters (similar large figures have been recorded from other locations in recent years).

The Bradshaw figures have generally been regarded as being shown mostly in group scenes, with few individual depictions. Crawford thought that isolated figures could have been relics from once larger scenes. Group compositions were common on the Drysdale, often frieze-like or in elaborate tableaus, but a number of examples of paired figures or lone figures were also found. These were often interspersed with other motifs. In some cases the isolated, lone examples seem to have been very deliberately placed, sometimes in secluded but prominent positions such as on a large boulder in a gully or, such as in the case of the superb Winged Headdress figure (Figure 4), in a shelter part way up the escarpment with extensive vistas over the river and surroundings.

Earlier recorders also noted that nearly all compositions contained only figures of people and there seemed little if any association with animal motifs. On the Drysdale a number of examples were found where finely painted animals, usually kangaroos, were included in the scenes with Classic Bradshaw figures. In one gallery a panel of Classic Tassel Bradshaws was found associated with macropod tracks, kangaroos, and a stingray (Fig. 6).

One of the most distinct examples of animals associated with Classic Bradshaw figures was found under a small overhang high on a sandstone bluff overlooking the river. This composition consists of two ornamented Bent Knee Figures and

Bradshaw (Gwion) Figures: Initial Observations Drysdale River, Kimberley 1986/88, Fig 6 Classic Tassel Bradshaws – macropods and stingray, Drysdale River

Bradshaw (Gwion) Figures: Initial Observations Drysdale River, Kimberley 1986/88, Fig. 7 Classic Bent Knee Bradshaw figures with rock possums, Drysdale River

three animals. Two of the animals are drawn equal in size to the figures and have been tentatively identified as rock possums (Fig. 7). The whole effect is reminiscent of a coat of arms. No other figures or symbols are present, and the total composition is of the same color and patination.

Little evidence of over-painting was found in the sites recorded, and most sites contained figures and motifs in a wide variety of styles. The Classic Bradshaw figures are distinct and easily recognizable and certainly represented a pinnacle in form, composition, and execution that ranks with any rock art to be found in Australia.

Simplified Bradshaws

Along with the Classic Bradshaw figures were examples of other figures, similar in many ways but with clear differences. Examples included lines of finely drawn figures in frontal perspective and holding hands, to very simple stick figures in chain-like arrangements. Most notable among these figures was a greater rigidity of perspective, a more stylized appearance, and a lack of fine detail. In addition, physical features such as musculature were less clearly delineated, and ornamentation was not as elaborate as with the Classic Bradshaws. Headdresses of varying designs, tassel waist-belts and sashes were still present but not as detailed as those of the Classic Bradshaws. Implements depicted included single-barbed spears, boomerangs, a stick-like baton, and dilly bags resembling a round object. The size range was from 10 to 30 centimeters.

In most cases the figures are in upright poses. However, in a number of examples, the figures are shown squatting, kneeling, and in one case sitting astride a log-like object which gives the impression of a watercraft. A single example was found sitting front-on in the lotus position, with face and hands turned to one side. Only one example was found which gave any indication of facial features in profile. This came closest to Joseph Bradshaw's original description of the figures he found having aquiline facial features.

Bichrome Figures with "Hooked Sticks"

Another distinct style evident was a series of bichrome figures. Many showed fine artistic execution similar to the Classic Bradshaw figures, but they generally lacked an equivalent degree of ornamentation and naturalistic physical detail. These figures tended to be more rigid and did not have the flowing appearance of the Classic Bradshaws. They showed evidence of originally having several colors, with the outline in dark red pigment and a white and yellow infill (Fig. 8).

Bradshaw (Gwion) Figures: Initial Observations Drysdale River, Kimberley 1986/88, Fig. 8 Bichrome figures from bichrome rock, Drysdale River

A common feature was gaps in the headdress and/or the hands and feet missing, probably where another color was used that has not bonded to the rock surface. In nearly all cases, they were associated with multi-barbed spears and a hooked stick that probably represents a spear-thrower.

Later surveys showed that many of these figures had more than one color, and Welch (1993a, b, 2015) later changed his original Bichrome descriptor to Straight Part Figures; Walsh (1994) termed them Clothes Peg Figures. Veth et al. (2018) describe them as Static Polychrome Figures.

Figures in Action Scenes

Numerous examples of finely painted red figures in action scenes were also found. These showed a wide variation in style and execution. They tended to be miniatures, ranging in size from 10 to 30 centimeters. All were drawn in shades of red ochre, varying from dark to bright red. Their most recognizable characteristic was the portrayal of dynamic action sequences, including groups running, jumping, and in scenes hunting kangaroos. They have no ornamentation other than a conical or wedge-shaped headdress. Weapons depicted were boomerangs and hand-thrown single-barb spears. Physical features are generally not shown in any detail although some exceptions occur. Nearly all such figures are silhouettes. As with the Classic Bradshaw figures, they appear to have bonded with the fine-grained sandstone and are like shadow images, with no trace of surface pigment.

In many ways these paintings were similar to the San art of southern Africa, although there is no evidence to suggest any links. In their fluid and delicately worked action scenes, these figures come closest, perhaps, to the Dynamic Figures of Arnhem Land. Both have clear representations of action, expressed with great power and feeling though the Arnhem Land examples tend to show a greater impression of movement.

One of the most impressive scenes discovered is a tableau hunting scene (Fig. 9). This shows a figure with a cone-shaped headdress running with arms outstretched and herding a group of finely detailed kangaroos toward another figure on the other side. The kangaroos are depicted closely bunched and jumping into each other in their attempts to escape. The composition is bright red, as though it was done only yesterday, yet there is no discernible pigment left on the rock surface, only an "imprint." This panel was at Nurini, one of the few sites where I was able to record the local traditional name.

Many of these paintings are similar to some of the Arnhem Land figures described by Mountford (1937). In his 1988 work, *Australia's Greatest Rock Art*, Walsh claims that the local Aborigines called

Bradshaw (Gwion) Figures: Initial Observations Drysdale River, Kimberley 1986/88,
Fig. 9 Kangaroo hunting scene panel from Nurini art site, Drysdale River

these figures "Kiera-Kirow," a variation of the term "Giro Giro" used by Worms to describe all pre-Wandjina art, including the style of red figures described here. These figures certainly are clearly distinguishable from the Classic Bradshaw figures and represent another stylistic variation. They do however have similarities with the Classic Bradshaw figures with regard to color, size, naturalistic presentation, and being impregnated into the rock like shadow images. They occur in the same areas and often the same shelter as Classic Bradshaws, giving rise to the possibility that they may be contemporaneous. Figures of this type were called Elegant Action Figures by Walsh (1994).

Other Motifs

Apart from the different styles among the anthropomorphic figures generally classed as Bradshaw, there is a large array of other motifs. Among them are mammals (including what appears to be a dugong and a whale's tail), fish, snakes, plants, some grotesque spirit creatures, handprints and stencils, and various apparently abstract designs and patterns.

Wandjina Figures

The recent Aboriginal art tradition of the Kimberley has been dominated by the Wandjina style. These dramatic paintings are characterized by white staring faces with prominent dark eyes and lashes, and most are surrounded by large haloes, often with radiating spikes emanating from them. Noses are depicted, but no mouths are shown. Wandjinas are the ancestral spirit beings and form an important part of the ongoing cultural and art tradition of the Kimberley.

Only three of the many sites recorded along the Drysdale contained Wandjina depictions. None of these paintings showed any sign of repainting, commonly recorded on other Wandjina sites, and none had the whitewashed background commonly associated with such figures. Among an extensive array of figures and motifs in one large shelter named as Yuruluru by Robert Unhango were two Wandjinas lying on their side and joined at the waist, and another depicted from the waist up (Fig. 10). All three had heavy red ochre haloes with radiating spikes. The eyes on these Wandjinas were accentuated with fine red lashes, and, typically, no mouths were shown. There was little to suggest any repainting in recent years, and the visual state and condition suggested considerable age. Unlike the Bradshaws and other finely painted motifs in the same shelter, the Wandjina paintings were deteriorating, and their pigments did not exhibit any obvious bonding with the rock surface. It was interesting that this site contained side by side virtually all the styles discussed here,

Bradshaw (Gwion) Figures: Initial Observations Drysdale River, Kimberley 1986/88, Fig. 10 Twin Wandjinas at Yuruluru, Drysdale River

including Classic Bradshaw figures, the superb miniature red figures in the kangaroo hunting scene already described (Figure 9), and a line of more rigid frontal perspective figures holding hands.

Research Since 1988

In the same year that I presented my paper at the AURA conference in Darwin in 1988, Darrell Lewis published a new analysis of the west Arnhem Land rock art sequence, focusing particularly on depicted material culture items. By comparing his analysis with the available information on Kimberley art, he found many striking similarities and parallel changes between certain styles of Bradshaw figures and particular styles of human figures in west Arnhem Land. He suggested that Bradshaw art could be divided into two consecutive periods, the first being dominated by Classic Bradshaws and the second involving different styles of Bradshaw figures, many of which were bichromes and carrying a "new" artifact, a hooked stick which probably represented a prototype spear-thrower. Lewis argued that these were the equivalents of the Arnhem Land Dynamic figures and the subsequent "Hooked Stick" figures. He suggested that when these styles were being produced, the two regions were culturally and temporally linked. Based on evidence from Arnhem Land, Lewis suggested that the Classic Bradshaws were of terminal Pleistocene-early Holocene age.

My 1988 paper sparked the interest of two noted avocational researchers, Grahame Walsh and David Welch. In the following years, Walsh and Welch independently undertook extensive recording and analysis of the Bradshaw art body, producing numerous papers and books. Both eventually proposed a more complex Kimberley rock art chronology than the preceding simple "Wandjina-Bradshaw" division (Welch 1990, 1993a, 2015, 2016; Walsh 1994, 2000).

Following extensive fieldwork recording over 700 sites, Welch proposed a three-phase chronological sequence which was expanded to six distinct periods. With no actual dating of the art, he based his chronology on pigment, weathering, content, spatial arrangement, and superimposition (Welch 1990). He presented this chronology at the 1992 AURA Congress in Cairns and refined it in his subsequent publications (Welch 1990, 1993a, 2015, 2016).

A chronology developed by Walsh (1994) was a highly elaborate sequence of styles, groups, and

subgroups of Bradshaw figures, and he suggested that most were considerably older than 20,000 years. He also saw three distinct stylistic phases and divided each of these into a number of subgroups (Walsh 1994, 2000). Lewis (1997) challenged Walsh's chronology as unnecessarily complex and showed that his dating suggestions were unsustainable and often contradictory. More recently the Kimberley style sequence has been further described by Travers and Ross (2016), Veth et al. (2018), and Scott-Virtue and Goodgame (2017).

The Kimberley Foundation Australia (KFA) is a major catalyst in leveraging funding and initiating a number of academic research projects. The first significant project, "Continuity and Change," examined aspects of the Kimberley rock art and was conducted by the late Mike Morwood and June Ross on Mitchell Plateau from 2009 to 2011. Their work was followed in 2014 and 2015 by two other extensive projects, the "Kimberley Dating Project 1" and "Kimberley Visions: rock art dynamics of Northern Australia." The dating project has now been extended as, "An absolute timescale for the Aboriginal rock art of the Kimberley region – landscape processes and multiple chronometers." It will apply new knowledge of the complex processes on sandstone surfaces across the north Kimberley, and an innovative combination of four scientific dating methods developed in the earlier work. The project expects to establish a well-dated sequence for Kimberley rock art based on replication of results and confirmation across different methods KFA (2019). An initial paper on the dating of fossilized mud wasp nests located on top of rock art motifs as a means to establish minimum dates has been published (Finch et al. 2019), and a forthcoming paper will provide some of the much sought-after dates for the rock art chronology. All these projects are multi-university, multidisciplinary, government, and philanthropically funded projects partnering with Traditional Owner groups.

Conclusion

The 1986 and 1988 Drysdale River surveys uncovered a substantial body of well-preserved and diverse rock art and extended the geographic range of Bradshaw art eastward from its previous known distribution. Surveys since 1988 have extended this distribution to most parts of the north Kimberley. An interesting feature of the art found in the Drysdale River National Park and surrounding areas is the rarity of the more recent Wandjina art styles. The concentration of Bradshaw art in this area is certainly significant and possibly among the largest found so far.

In 1988 I remarked that the coexistence of such a large concentration of seemingly different art styles in the region could help future researchers develop insights into the stylistic development of the art in the northeast Kimberley. I suggested the possibility that few firm conclusions may be possible but that there surely was enough information available in the surviving images to provide an excellent picture of some of the social aspects of a people who have passed with time. The skill and elegance of these figures as depicted on the walls of the shelters remain a true joy to all those fortunate to behold this treasure of our national heritage.

The systematic exploration and recording program I began in 1988 has continued annually until the present time. Through much the same period, similar work was carried out on nearby Theda Station by Grahame Walsh and at Faraway Bay west of the King George River by Lee Scott-Virtue and Dean Goodgame. The result of this work was to highlight the extent and complexity of Kimberley rock art, particularly the art body preceding the Wandjina period. Well over 2000 sites have been recorded in these locations. Most recently works by research teams from the University of Western Australia (UWA) and Melbourne University have added further to the number of previously recorded sites and indicate that the Drysdale National Park, nearby Theda and Doongan stations and the King George River, has one of the highest concentrations of recorded rock art sites in the Kimberley (Veth et al. 2018).

Post Script

Since the initial discoveries in 1986 of a major rock art body along the Drysdale River and particularly in

the northern section of the Drysdale River National Park, there have been substantial developments in surveying and recording and new analyses of what is clearly a rock art heritage of world significance. This focus of this work has been especially directed to the distinctive, naturalistic Gwion or Bradshaw figures and associated stylistic variations.

News of this art find in the media and my presentation at the first Australian Rock Art Research Association (AURA) Congress in Darwin in 1988 precipitated a flurry of avocational activity and also a substantial increase in the numbers of recreational and commercial bushwalkers who found and recorded parts of this widespread art body, along with the extensive discoveries and recordings by Schmiechen, Walsh, Welch, Donaldson, Scott-Virtue, and Goodgame in the north and northeast Kimberley. Over the last 30 years, over 900 additional sites have been recorded by Donaldson, and examples from his work have appeared in his three volumes on Kimberley rock art (Donaldson 2012, 2013a, b).

The growing publicity since the late 1980s has placed national and world attention on the diversity, antiquity, and preservation of this dramatic body of rock art in the Kimberley. It is a powerful statement of Aboriginal culture imprinted into the landscape. Aboriginal people have now regained title to much of the Kimberley and are increasingly working in partnership with the new wave of academic researchers to document and analyze this amazing body of rock art. The challenge for the future is how to tell the story and share and value this cultural heritage with future generations as an integral part of Australia's deep history.

Braidwood, Robert John

Patty Jo Watson
Department of Anthropology, Washington University, St. Louis, MO, USA

Basic Biographical Information

Robert John Braidwood (Fig. 1) was born July 29, 1907, in Detroit, Michigan. He completed a degree in architecture at the University of Michigan in 1929 and spent several months in an architectural office. However, the Great Depression made his future as an architect tenuous. He decided to go back to school to take courses in anthropology, a field that had interested him during his undergraduate years. He took an ancient history class taught by Leroy Waterman, director of the University of Michigan excavations at Tell Umar (the ancient city of Seleucia) in Iraq. Braidwood's skill at drafting and free-hand lettering made such a positive impression on Waterman that he invited the young man to join the 1930–1931 season at Seleucia as surveyor and draftsman. Braidwood returned to Michigan to complete his B.A. (1932) and M.A. (1933) in anthropology and was then hired (1933–1938) by the University of Chicago's Oriental Institute as field assistant to the Syrian Expedition working

Braidwood, Robert John, Fig. 1 Braidwood with Jarmo artifact, Oriental Institute, University of Chicago, c. 1965. (Photo courtesy of P. J. Watson)

in the Amuq (the Plain of Antioch). In 1937, he married Linda Schreiber, whom he had first met during their undergraduate years at Michigan, the two forming a team that endured for the next 66 years. In 1938, he entered a doctoral program at the Oriental Institute (also taking coursework in Anthropology), which he completed in 1942. From 1941 to 1945, Braidwood was a part-time faculty member of the University of Chicago. In 1945 he was promoted to professor with joint appointments in the Oriental Institute and in Anthropology, a position he held until his retirement in 1978. He and Linda continued to participate in the Turkish Prehistoric Project for several more years.

Braidwood was the first archaeologist to seek empirical evidence (floral and faunal remains) for the beginnings of agriculture and pastoralism in Western Asia. He began his work initially at the site of Jarmo in northern Iraq (Braidwood and Braidwood 1950, 1953). Funding from the US National Science Foundation in 1954–1955 (the third Iraq-Jarmo Project field season) enabled Braidwood to add a botanical expert, a zoologist, a geologist, and a radiocarbon specialist to his field staff. When the 1958 nationalist revolution in Iraq made fieldwork there impossible, he transferred this collaborative research team to Iran (the Iranian Prehistoric Project 1959–1960) and then to Turkey (the Joint Turkish Prehistoric Project-Istanbul/Chicago, Diyarbakır region, 1963–2003) (Braidwood and Çambel 1980). Jarmo was the first "oldest food-producing community" to be revealed, the precursor of many other such communities now known in the Levant, Turkey, Iraq, Iran, and elsewhere (Braidwood 1967, 1973; Braidwood et al. 1983). Archaeologists around the world have joined the Braidwoods in pursuing evidence for the origins of plant and animal domestication and of food-producing economies in many regions of Asia, Europe, Africa, Oceania, and the Americas.

Braidwood received numerous honors over his career. He was elected to the National Academy of Sciences, the American Academy of Arts and Sciences, and the American Philosophical Society. He was made a foreign correspondent or honorary fellow of the German Archaeological Institute, the Austrian Academy of Sciences, and the Society of Antiquaries. He was also awarded honorary degrees by the Sorbonne and the University of Rome. In 1971, the Archaeological Institute of America presented him with its Gold Medal for Distinguished Archaeological Achievement, and the American Anthropological Association designated him its Distinguished Lecturer in Archaeology. In 1995, the Society for American Archaeology awarded him the Fryxell Medal for Interdisciplinary Research in Archaeology.

Major Accomplishments

The "agricultural revolution" is foundational to the origins of urbanized, state-based civilization in southern Mesopotamia. Braidwood's interest in the topic derived in part from publications by Harold Peake and Herbert Fleure (*The Corridors of Time*, eight volumes, Yale University Press, 1920s–1930s), V. Gordon Childe (1934), and Raphael Pumpelly (1908). His primary accomplishment was introducing, demonstrating, and advocating interdisciplinary archeological field research aimed at recovering primary evidence (physical remains of the earliest plant and animal domesticates) documenting agropastoral origins in western Asia. Moreover, he initiated a major

conceptual shift regarding West Asian agricultural origins when he based his fieldwork program – not in the lower Tigris-Euphrates region – but rather in the natural habitat zone of the first domesticates (e.g., goats, sheep, wheat, barley, legumes): rain-watered uplands above the irrigation-based, earliest Mesopotamian cities. He referred to this nuclear zone as "the hilly flanks of the Fertile Crescent" (Braidwood and Braidwood 1950, 1953; Braidwood and Braidwood et al. 1983).

Braidwood also implemented a radical change in the organization of Near Eastern fieldwork. Fieldwork was traditionally carried out at big sites employing dozens, even hundreds, of workmen whose main job was to open up large-scale exposures of architectural remains. Recovery of artifacts was centered primarily on those that were complete or nearly so, beautiful, or intrinsically interesting to those directing the excavations. Braidwood's crews of workmen were smaller and much more closely supervised by field staffs that included botanical, geological, and zoological experts at a time when the collaborating scientists had to bootleg field and analytical time from their regular jobs. It was only many decades after the NSF-funded Jarmo field season of 1954–1955 that new subdisciplines of archaeobotany/paleoethnobotany, geoarchaeology, and zooarchaeology came to characterize modern archaeology.

Another of Braidwood's accomplishments was to highlight the period immediately preceding the first appearance of established agropastoral economies. He called this the "era of incipient food production" and was the first archaeologist to direct attention toward elucidating key characteristics of those Early Holocene foraging/hunting-gathering peoples who created the first agricultural and pastoral economies.

As early as the 1950s, Braidwood was also advocating ethnographic research in Near Eastern villages where many ancient techniques and practices (e.g., building and maintaining adobe or puddled-adobe structures; caring for mixed flocks of sheep and goats and processing their wool, hair, and milk; growing and processing wheat, barley, and legumes) were so successful that they could still be seen and documented thousands of years later in contemporary communities (e.g., Watson 1979; Kramer 1982).

Braidwood's primary contributions to archaeological knowledge center upon his research and publications concerning one of the most important transitions in the human past, namely, the origins of agriculture and pastoralism in western Asia. His work on this topic inspired an international research trajectory whose practitioners continue to expand, revise, and refine knowledge of agricultural and pastoral economies ancestral to the array of food-producing systems currently supporting human societies upon this planet.

Brazil: Cultural Heritage Management Education

Paulo Deblasis and Cristina Bruno
Museu de Arqueologia e Etnologia (MAE), Universidade de São Paulo (USP), São Paulo, Brazil

Introduction

Although cultural heritage management (CHM) has become a legal and effective concern in Brazil since the end of the 1980s, professional training as regards its legal and methodological specificities is still at its beginnings, mostly due to an apartheid between "archaeological" (i.e., Native-American) and "historical" (colonial or more recent) heritages. While historical heritage has long been recognized and explored, usually by means of historical and architectural perspectives (with museological/educational resonances), most of Native American heritage remained within academic research circuit and under specific legal protection background. This has promoted little concern for issues such as site management and collections curatorship, as well as its use for educational approaches.

Historical Background

The development of an "official Brazilian culture" (since Independence Day) has segregated Native American societies (and their material record) into the "ghetto of the exiled memories," that is, their existence is known but from a very exogenous and diffuse perspective (Bruno 2007). Thus, Native cultural contents have been systematically kept outside from formal education, as well as from the first legal diplomas (from 1937) regarding national heritage, focused, as they were, on "historical" heritage. The first "national museums," appearing by the end of the nineteenth century, are historical in nature and devoted also to Natural History and Ethnology. There is interest in archaeological research, but it has never been considered mainstream at any official institution, the first formal archaeologist been hired only in the 1920s. But, interestingly, these museums have gathered, since their very beginning, several important archaeological collections assembled by amateurs or naturalists, usually treated as of secondary importance.

From the 1950s on, systematic archaeological research takes off, but the predominance of research interests led by foreign initiatives (or "missions") prevents adopting the notion of management as a priority. In the following decades (up to the 1990s), most archaeological investigations have been performed by academic research groups housed at universities, usually

more concerned with scholarly perspectives than management approaches (Funari 2004).

Heritage management in Brazil has appeared as a way to cope with the increasing destruction of archaeological remains due to fast economic development. This is the spirit of the first archaeological law, from 1961: to preserve, it is necessary to prevent/punish the destruction. With a few exceptions, there is no concern as regards management or education. Through the following decades, the IPHAN has been responsible for the protection and management of archaeological sites and collections, but with a legal and operational apparatus apart from historical/architectural sites and also strange from general national politics on museums and historical heritage management. (The Instituto do Patrimônio Histórico e Artístico Nacional – IPHAN (National Historical and Artistic Heritage Institution), established in the 1930s, has always been a reduct of architects; the first archaeologists have been hired only in the 1980s).

The formidable expansion of preventive (or "contract") archaeology (CRM projects) since the end of the 1980s and the overwhelming multiplication of recorded archaeological sites have evinced the need for the development of heritage management plans and strategies in three different levels: legal (with more specific diplomas regarding how to proceed as regards archaeological contexts), educational (law-enforced inclusion of heritage education programs into CRM projects), and museological (regarding the organization and management of the archaeological collections). Again, it must be stressed that these policies have been developed with no formal connection with established national heritage and museums programs, having a legal and operational apparatus on its own (for a more comprehensive review see DeBlasis 2010).

Current Debates

Heritage Management and Archaeology in Brazil: The Status of Art

As stated above, the inception of "education" into archaeological professional and academic career is recent and law-enforced in Brazil, becoming mandatory in every single research project since 2002. Legal diplomas, albeit well intentioned, have created a sort of "cake recipe," a report formula that (re)produces rather innocuous results from a scientific and educational standpoint, unfortunately supported by regulating agencies.

Education through, or for, heritage has long been an important concern into museums relationship toward the public (especially art education) and other means of scientific diffusion, as well as interpretive communication (tourism), particularly as regards historical heritage. These programs have strongly benefited from the development of robust pedagogical approaches such as the well-known *liberation education*, essentially based in learning and enhancing critical consciousness from the concrete experience of the surrounding reality (Freire 2000, 2005) and "educational city," enhancing urban identity and citizenship. There is also a strong focus on environmental education and sustainability, as well as education toward social inclusion, mostly among risk groups. Museological pedagogy, exploring communication through collections/landscapes and using memory indicators (and the so-called places of memory), has also known an enormous development, together with heritage education through material/cultural evidence (Horta 1984; Hooper-Greenhill 1995).

Particularly as regards archaeology, educational efforts have been confined to a few museums (usually linked to universities), focusing on the scientific perception of the discipline and exploring, occasionally, experimental archaeology. Through the last 10 years, a bigger concern with public archaeology has emerged, due to the growing awareness, by archaeologists, of the social, ethnical, and political problems involved on the praxis of their profession (DeBlasis 2010). A very interesting case came out within a project near the Xingu indigenous reservation, located at the southern Amazonian area, where archaeology (and archaeologists), with the support of the IPHAN, has led local community interests to be included into the scope of the project and to the creation of additional reservation territories based on indigenous knowledge.

Future Directions

Although it is possible to recognize the existence of advanced heritage legislation in Brazil, well tuned to environmental and sustainability perspectives, it is still poorly connected to formal education. Curiously enough, the management of archaeological heritage has taken an alternate path, apart from the mainstream educational tendencies and divorced from national museums politics. The protection of archaeological collections is a nuclear management problem today, due to its impressive accumulation in regional museums appearing everywhere, with few curatorial concerns. Despite the recent multiplication of grad schools of archaeology all over the country, the attention given to these and other management problems is still very timid. The distance between standard research procedures and effective management initiatives, on one side, and formal heritage education, on the other, needs urgent bridging. This rather peculiar situation, that is, the absence of site and collections management issues at the school curricula, as well as the overwhelming expansion of CRM projects all over the country, jeopardizes the continuity and acquisition of higher standards in heritage education in Brazil.

Besides these difficulties, public outreach of the archaeological heritage studies, whether academic or CRM based, is slowly growing, and in fact archaeologists themselves have become more attentive to it. Cultural sections of the most important newspapers show full-page texts on brand new discoveries; ecological TV programs bring archaeological reports every now and then, and easy reading books for the general public have also been published. Public education has become one of the forefront activities on recent archaeological research projects, and archaeologists now go to local schools and community centers to speak about the past, the environment, the things they find, history, and material culture – after all, what the hell are they (we) doing? It also has become common seeing flocks of school kids visiting archaeological excavations, often conducted by trained guides. Important to remember, public education has become mandatory in CRM projects from 2002 on, and these activities also must be reported at the project outset. But very often, unfortunately, the lack of prepared personnel brings, to these opportunities for effective educational contact and interaction, a rather deceptive outcome.

To overcome this situation, CHM education must be expanded to encompass a fully humanistic, as well as technical, professional formation for archaeologists and heritage managers. Archaeological practitioners need to go beyond descriptive standards and normative interpreting categories. They must dare to incorporate the living landscapes into their imaginary and cartography and realize that their work makes a difference for a more encompassing, socially and environmentally diversified future.

Brazil: Historical Archaeology

Luís Cláudio Pereira Symanski and Andrés Zarankin
Departamento de Sociologia e Antropologia, Universidade Federal de Minas Gerais, Belo Horizonte, Minas Gerais, Brazil

Introduction

Following a general trend in South America, historical archaeology in Brazil has experienced a growth since the mid-1980s. This contribution reviews its history and development, particularly in the last 20 years. It begins by focusing on the wider South American context and proceeds with an analysis of some of the most outstanding projects undertaken in Brazil over the last two decades or so.

Definition

Historical archaeology in Brazil is a field that started to be developed in the 1960s, initially without any difference, whether in goals or in methods, from the prehistoric archaeology. In the last 20 years, it has had a significant development, insofar as the focus on a descriptive culture-historical approach has being gradually substituted by approaches more influenced by contemporary social theory. In recent decades, Brazilian and other South American historical archaeologists, in an effort to move away from the strong influence of North American historical archaeology, have been concerned with building a proper identity for the field, based on the historical and cultural particularities of South American countries (Funari et al. 1999; Lima 1999; Senatore and Zarankin 2002).

Historical Background

Historical Archaeology in South America

The emergence of historical archaeology in many South American countries occurred concurrently with the development of prehistoric archaeology, during the first half of the twentieth century; however, it was only in the 1960s that more systematic studies started to take place. During the 1960s and 1970s, research on historical sites was usually conducted by non-archaeologists – amateurs, historians, and architects (Lima 1993; Funari 1994). Basically, their investigations shared as a main goal the contribution towards the building of national identities based on the colonial European splendor. These early works are characterized by a set of common features, such as the straightforward correlations between material culture and documentary data, the rescue of valuable historic artifacts and structures, and supplying information for restoration projects.

It was only in the 1980s that archaeology in South America started to develop as an independent field of knowledge, being recognized its potential in the construction of alternative discourses about the past. As a consequence, historical archaeology started to enjoy an independent status for the first time. In this way, archaeologists began to create multiple visions about recent history, which could be opposed to or different from official history or "master narratives."

This multiplication of counter-hegemonic discourses was closely related to the end of military dictatorships and the consolidation of democratic governments in Latin America (Funari 1994). The new sociopolitical context allowed archaeology to experience an accelerated growth, a process which was particularly intensified during the 1990s. This growth was reflected in the development of several research programs that focused on the study of diversified problems and regions, in the creation of specific courses in undergraduate and graduate programs, in the spread of national and international meetings, and in the increasing number of publications.

Historical Archaeology in Brazil

Historical archaeology in Brazil (Fig. 1) emerged during the 1960s, when some scholars started to give attention to southern Jesuit missions from the seventeenth and eighteenth centuries in the states of Paraná and Rio Grande do Sul and to northeastern European-indigenous contact sites from the sixteenth century in the state of Pernambuco (Lima 1993). Most of these former historical archaeologists had been trained as prehistorians in that same decade to participate on a wide research program, the Programa Nacional de Pesquisas Arqueológicas (National Program of Archaeological Research), coordinated by Betty Meggers and Clifford Evans, from the Smithsonian Institute. This program identified some of the major archaeological complexes for the Brazilian territory. These archaeologists, following the goals of the culture-historical approach, were concerned with the identification and spatial-temporal delimitation of complexes of artifacts. Such complexes, named traditions and phases, were considered as material correlates of specific prehistoric cultures. In the case of the historical sites, the major focus was on pottery, analyzed with the purpose of building typologies to be inserted in specific historical phases and traditions (e.g., Symanski 2009). Although subjected to several criticisms, this approach was productive during the 1960s and 1970s, when scholars such as Igor Chmyz, Marcos Albuquerque, José Brochado, and Pedro Mentz Ribeiro studied the locally made pottery found in European-indigenous contact sites. Their goal was to discuss acculturative processes involving indigenous populations in contact with colonizers, an issue that continued to be approached up to the mid-1980s.

During the 1970s historical archaeology in Brazil experienced a slow development. Among its major accomplishments was its insertion in restoration projects of architectural national monuments, like fortresses and churches, but employed as a mere technique, totally subordinated to architecture. As new perspectives appeared in the 1980s, archaeologists became increasingly conscious of the potential of the discipline to investigate subjects that could lead to reinterpretations of the official history, such as unprivileged groups, social memories, and daily practices (Lima 1993). In this way attention started to be given to more ordinary kinds of sites. Tania A. Lima and Margarida D. Andreatta began to study urban and rural households in São Paulo and Rio de Janeiro, while Carlos M. Guimarães excavated maroon settlements in Minas Gerais. Paulo E. Zanettini (e.g., 1996), in turn, studied the peasant village of Canudos, in Bahia, which was the core of a messianic movement of contestation violently suppressed by the Brazilian army in the early Republican period (1896–1897).

Although most of the works undertaken in historical archaeology in the 1980s were still descriptive in nature, some scholars started to apply more analytical approaches. This was the case of Carlos Guimarães' study of settlement patterns in maroon sites of Minas Gerais (e.g., Guimarães 1988) and of Tania A. Lima's and Paulo E. Zanettini's studies on the relationships between European wares and household socioeconomic variability in Rio de Janeiro (e.g., Lima 1995) and São Paulo.

Key Issues/Current Debates

The 1990s witnessed an increasing interest in types of sites that had been overlooked until then. These included mining areas, collective trash dumps, colonial houses, slave quarters,

Brazil: Historical Archaeology, Fig. 1 Map of Brazil showing the locations mentioned in this text

cemeteries, colonial roads, and plantations. This diversification was largely the result of two factors: the establishment of contract archaeology, which slowly emerged in the previous decade, and the expansion of graduate programs in archaeology (Symanski 2009). Regarding the theoretical landscape, the setting established since the 1990s has been characterized by a diversity of influences, including processual, symbolic, post-structuralist, and critical approaches.

The processual approach influenced urban archaeology projects in the cities of São Paulo and Porto Alegre, through the systemic concept of city site, and consumer behavior studies concerning the relationships between European wares and household socioeconomic status (Symanski 2009). In the cities of São Paulo and Porto Alegre, the concept of city site has been used as a heuristic tool in general programs of cultural resources management developed by these cities' town halls cultural offices. The goal has been to consider any site located in the urban space as a product of the wider urbanization process and thus to study the material remains of this process and their relationship with the development of urban lifeways. Consumer behavior studies, in turn, have focused on the variability of nineteenth-century European wares in urban and rural contexts, discussing, on one hand, diachronic changes in these items as related to changes in social practices in direction to a Western European ideal of domesticity and, on the

other, synchronic changes according to specific social and cultural backgrounds that could have influenced the consumers' choices. These studies have demonstrated that European ideals of consumption were far from being uniformly incorporated by the Brazilian society, rather, distinct social and cultural groups attributed distinct sets of value to these items, in some cases, as those of the urban elites, emulating European tastes and social behaviors but in others, as seem to have been the case with some farmers, peasants, and slaves, rejecting or adapting such values according to local cultural logics.

In the mid-1990s, Tania Lima published three articles that can be considered the foundations of the post-processual historical archaeology in Brazil (Lima 1994, 1995, 1996). Based on a strongly poststructuralist perspective, she studied the practices and representations of nineteenth-century society in Rio de Janeiro and the ways in which this changed as a result of European-influenced ideals of modernization that were increasingly incorporated during the second half of that century. Through the analysis of contexts which included cemeteries and households, Tania Lima discussed issues such as the representations linked to death, practices of personal hygiene and health, and the habits and rituals involving the social and private consumption of meals. During this same period, Pedro Funari was engaged in developing a critical and interpretative program for Brazilian historical archaeology, discussing the disciplinary status of the field, the relationship between written documents and material culture, and the rescue of the history of underprivileged and marginalized groups (Funari et al. 1999). These works represent the starting point of the development of works that, since then, have explored a diversity of issues including power relations, gender, social and cultural identities, and the structuring role of the built environment and landscape.

In Brazil, as in other Latin American countries, there has been a strong focus on the processes of change caused by the development and expansion of industrial capitalism. This system produced changes in practically all spheres of social and private life, including the separation between domestic and working spaces, the segmentation of meals, the mechanical measurement of time, the intensification of the process of urbanization, and the adoption of European-influenced ways of life. Although the influence of North American historical archaeology perspectives regarding these issues is undeniable, archaeologists studying the emergence of modern society in Latin America have tended to highlight the economic, social, and cultural specificities of this region (Lima 1999; Funari 2002; Senatore and Zarankin 2002). A case in point is Tania Lima's research which focused, on the one hand, on the strategies developed by the European industrialized countries, through the imposition of ideologies and practices involving the growing consumption of their industrialized items, and, on the other, on the creative ways in which Brazilian society was able to mix these practices with its own traditions, creating hybrid expressions (Lima 1999). Some scholars, like Ana Sousa, Luis Symanski, and Fernanda Tocchetto (e.g., 2003), have followed this line of investigation, discussing how groups with distinct social and cultural backgrounds, such as urban merchants, planters, industrial laborers, peasants, and slaves, differentially incorporated, rejected, or even ignored the ideology of industrial capitalism, despite the ubiquity of European industrialized items in these sites.

Landscape archaeology is another avenue of inquiry that has revitalized Brazilian historical archaeology in the last decades. Pioneering these approaches was Tania Lima's (1994) study on the representations of death in the nineteenth-century cemeteries of Rio de Janeiro. In this work she discusses the ways in which changes in these representations were related to wider changes in the social, economic, and political dimensions of Brazilian society, during its transition from the Imperial to the Republican period. Subsequent works include Marcos Souza's study of the socio-spatial organization of a southern colonial fortress in Laguna (Santa Catarina state) and its role as an expression of the colonizing ideology of the Portuguese Crown (Souza 1995); Ana Souza's analysis of the role of a southeastern colonial road in the production and reproduction of social relationships among its users, including planters, peasants, merchants, slaves, and travelers (Souza

1995), and Beatriz Thiessen's discussion of the ways in which the façade and Greek-style sculptures of an early twentieth-century German-Brazilian beer industry in the city of Porto Alegre expressed the discourses of an emerging bourgeois in the early Republican period (Thiesen 2006). Landscape approaches have been applied as well in plantation archaeology. This is exemplified by Marcos Souza's discussion of the arrangement of the landscape of the plantation – *engenho* – São Joaquim, in Pirenópolis (Goiás state), which was constructed according to Enlightenment ideals that created differentiated temporalities among planters and slaves (Souza 2007). Symanski's (2007) study on the tactics applied by enslaved groups to subvert the hierarchically organized space of the plantations of Chapada dos Guimarães (Mato Grosso state) is another good example of a landscape-scale analysis.

The processes of construction and maintenance of ethnic and cultural identities have also received growing attention from scholars. Regarding the archaeology of southern Jesuitical missions, Fernanda Toccheto's work represents a departure from the traditional focus on acculturation, approaching the maintenance of traditional techniques of ceramic production among the indigenous population as a strategy of cultural resistance to Jesuit domination (Tocchetto 2003). It must be noted that since the 1990s, research on the Jesuit missions decreased insofar as archaeologists started to study the material remains related to African slavery. Research of this kind of context was inaugurated by Carlos Guimarães in 1980, as aforementioned. In 1990, Carlos Guimarães and his colleagues excavated the Quilombo do Ambrósio, recovering a significant amount of low-fired earthenware, pipes, and zooarchaeological material. In 1992 and 1993, Charles E. Orser, Pedro Funari, and Michael Rowlands conducted research on the largest maroon settlement known from Brazil, namely, the seventeenth-century Quilombo dos Palmares, located in the state of Alagoas (Funari 1999). They recovered indigenous and colonial coarse earthenwares and European majolicas. Additionally, early in the 1990s, Tania Lima and colleagues excavated the slave quarters of the coffee plantation São Fernando in Vassouras (Rio de Janeiro state), recovering a small assemblage composed of European whitewares and glass fragments (Lima et al. 1993). This scarcity of material was interpreted by the authors as indicative of the slaves' very low standards of life and supported the idea – currently surpassed – that the contexts of African slavery in Brazil were characterized by the paucity of material culture.

More recently, research on plantations in Central, Western, and Southeastern Brazil, carried out, respectively, by Marcos Souza, Luis Symanski, and Camilla Agostini, has revealed a large amount of material items related to slave lifeways, including coarse earthenware vessel forms such as pans, bowls, and storage jars; European whitewares consisting of plates, cups, saucers, and bowls; glass bottles, copper ornaments, and iron tools. Discussions regarding these artifacts have taken into account their role in the building of a sense of collectivity in the slave community, the development of an internal economy in the slaves quarters, the affirmation of discrete identities in the plantations space, and the existence of a market specifically directed to slaves and African-descent consumers, characterized by low-price commodities such as coarse earthenwares.

A growing interest in the archaeology of African-Brazilian experience has encouraged scholars to apply models of cultural encounters more sophisticated than acculturation, which, traditionally, has been the dominant model in the study of Jesuit missions and Euro-indigenous contact sites. This is the case with models of creolization, transculturation, and ethnogenesis, which tend to highlight the selective appropriation and reinterpretation of the culture of the "other," as well as the mutual cultural influence between colonizers and colonized, which results in the emergence of new cultural forms. The case of the Quilombo dos Palmares has been approached from the perspective of such models by Scott Allen, who has studied the ceramics from this site, and Pedro Funari (1999), who highlighted the multicultural configuration of this maroon settlement and the processes of interaction between maroons and other groups that occupied the region.

Marcos Souza (2000), in his study of the colonial mining village of Ouro Fino (Goiás state), has discussed the ways in which a culturally diversified population, composed by Portuguese, Portuguese-Brazilians, Amerindians, Africans, and African descents, used regionally made material culture to build a wide sense of regional identity founded over a baroque worldview. Nevertheless, this effort to build a common creole culture was rejected in the domestic sphere, where Souza notices the maintenance of strong ethnic and gender asymmetries, expressed in the dichotomy between European majolicas and the locally made pottery, which reflected the differences between white men and enslaved women of African descent.

The research carried out by Marcos Souza and Luis Symanski (2009) on three sugar plantations and one maroon settlement in Chapada dos Guimarães (Mato Grosso state) addressed the process of creolization of African and African-descent groups through a diachronic perspective on the period between 1780, when the first sugar plantations were established in the region, and 1888, when most of these establishments were abandoned due to the abolition of slavery in Brazil. In the earlier decades, the African component was restricted to a low number of regional identities, predominantly from the Mina Coast, in West Africa, and from Benguela, southern Angola, and the locally made pottery presented little decorative variability, predominating designs in zigzags, diamonds, and waves, generally incised over exposed coils in the upper part of the vessels. This setting changed during the second third of the nineteenth century, when large numbers of Africans, from Western, Central, and Eastern Africa, arrived in the region and Mina and Benguela slaves strongly dropped in number. The locally made pottery from the contexts of this second period, in turn, presented a much larger decorative variability, with the introduction of new techniques, such as stamped, impressed, punctured, and finger-nailed decoration, in a wide diversity of motifs and combinations. Finally, in the last third of the nineteenth century, a creole generation, which was born on these plantations, started to dominate the demographic regional setting, coming to represent more than three quarters of the slave population in the 1870–1888 period. During this period, decorated vessels strongly dropped in popularity, demonstrating that the decorative dimension of the locally made pottery had little significance to this more culturally homogeneous, creole generation. These correlations suggested that Africans used these items to express cultural differences whereas African-Brazilians did not, demonstrating that in this region, the process of creolization was strongly linked to generational changes in the slaveholdings.

Marcos Souza has also studied the slave quarters of the São Joaquim sugar plantation in Pirenópolis (Goiás state), focusing on the active role that material culture exerted in the social universe of the enslaved groups. He concludes that the process of creolization in that context involved the formation of a coherent cluster of references by those groups, which was constantly recreated and reinvented over the generations (Souza 2007).

Another field that has seen significant development in recent years is underwater historical archaeology, particularly through the work of Gilson Rambelli (e.g., 2002), who has studied shipwrecks along the Brazilian coast. Rambelli has created a Laboratory of Underwater Archaeology and is responsible for the formation of a new generation of Brazilian underwater archaeologists.

Also, Pedro Funari has recently raised awareness among Brazilian archaeologists the diverse issues regarding archaeological practice, the political enrollment of archaeologists inside the local communities in which they work, and the effects that interpretations about the past can have over the present. The growing importance of these discussions has led Funari to create a Public Archaeology Center at the University of Campinas, São Paulo (Funari 2004). This focus on the political role of archaeology has also led to the emergence of new issues, such as the archaeology of repression (Funari et al. 2009), the decolonization of the discipline, and the development of what Daniel Miller has termed "material culture studies," which involves the archaeology of present daily life (Zarankin 2010).

International Perspectives

Although most of the academic production in historical archaeology in Brazil is still directed just to a national or sometimes Latin American audience, this picture has tended to change since the 1990s, when some Brazilian archaeologists started to discuss the singularities of social conformation at the local level, highlighting the role of agents in the definition of the practices they use to construct their identities (e.g., Funari et al. 1999; Lima 1999, 2002). The work of Pedro Funari and Tania Andrade Lima, especially, is well known internationally, being frequently cited in articles and books in Europe and United States. Currently, Brazilian historical archaeology is entering a phase of growing internationalization, with an increasing number of scholars publishing articles in some of the major international journals dedicated to the field. It must also be noted that Brazil has had an important role in the development of historical archaeology in Latin America in this century, particularly by spreading academic research results. This is in great part due to the publication, since 2008, of the journal *Vestígios – Revista Latino-Americana de Arqueologia Histórica*, a biannual periodical edited by Andrés Zarankin and Carlos Magno Guimarães and published by the Federal University of Minas Gerais, the aim of which is to promote interaction between scholars working in the field of historical archaeology across Latin America.

Future Directions

In the last 20 years, Brazilian historical archaeology has attained a state of maturity, constituting a fully integrated field of study in the country's research agenda. The heterogeneity that currently characterizes the field is also its major strength, insofar as it guarantees a plurality of perspectives, critical for the building of more inclusive, multivocal pasts, which are essential for the social development of a country historically characterized by enormous social inequalities. The current development of the field in Brazil illustrates a growing concern with the study of underprivileged groups, such as slaves, peasants, immigrants, Amerindians, and urban proletarians. These studies will serve not only to highlight the living and working conditions and identities of these groups in the past but also to strengthen the memory and identities of the contemporary descendant communities, insofar as public archaeology has been growing as an important part of archaeological agenda in academic as well as in cultural resource management researches.

Breadfruit: Origins and Development

Nyree J. C. Zerega
Northwestern University and the Chicago Botanic Garden, Evanston, IL, USA

Basic Species Information

Taxonomy

Breadfruit has been a major staple crop for millennia in the islands of Oceania, where hundreds of cultivars have been developed and named. The first accepted botanical description of breadfruit dates back to 1773 by Sydney

Parkinson, one of the artists who accompanied Joseph Banks on the voyage of the *Endeavour*. Since then a proliferation of names for breadfruit and its close relatives have been published, leading to much confusion in the literature about the correct scientific name for and the delimitation of the domesticated breadfruit. Recent examination of both morphological and molecular characters of hundreds of samples of breadfruit from throughout Oceania as well as related species has lead to a better understanding (Zerega et al. 2005a). The domesticated breadfruit is *Artocarpus altilis* (Parkinson) Fosberg (the most commonly seen synonyms include *A. communis* (Forster) and *A. incisa* (Thun.) L.f.). Two closely related species that contributed to breadfruit domestication are *A. camansi* Blanco and *A. mariannensis* Trécul (Fig. 1). Hybrids *A. altilis x mariannensis* also exist (Fosberg 1960).

Species Description

Artocarpus altilis is a large evergreen tropical tree that can reach up to 30 m tall. It is monoecious with separate male and female inflorescences on the same tree and produces copious amounts of white sticky latex throughout the plant. There is great diversity in the leaf and fruit (breadfruit is technically a compound fruit) characteristics of breadfruit. Adult leaves are typically glossy, dark green, and pinnately lobed and range in size. The number and size of the lobes can vary greatly, with some cultivars having no lobes at all. Fruits are variable in size (up to 20 cm wide × 30 cm long), skin color (typically yellowish to greenish), flesh color (creamy white to pale yellow), surface texture (smooth, bumpy, or spiny), and whether or not seeds are present. Seedless cultivars are typically triploid.

Although the tree is primarily grown for its starchy fruit, it is a multipurpose crop. The tree itself is used in multicropping agroforestry systems in the tropical Pacific Islands. The wood is prized for its resistance to termites and is used for dugout canoes, carvings, and in construction; the bast fibers can be used to produce cloth and cordage, the latex can be used as an adhesive, for caulking or birdlime; and all parts of the tree are

Breadfruit: Origins and Development, Fig. 1 Breadfruit and its relatives. Fruit surface and cross sections of *A. camansi* (**a**, **d**), *A. altilis* (**b**, **e**, **f**), and *A. mariannensis* (**c**, **g**)

used for a variety of medicinal purposes (Jones et al. 2011a).

Geographical Distribution

Oceania is home to the greatest morphological and genetic diversity of breadfruit, and this is where the crop was originally domesticated. In the eighteenth century, Europeans began distributing a select few cultivars beyond the Pacific Islands and today it can be found in over 80 countries throughout the tropics. However, the diversity of cultivars outside of Oceania is extremely low (Zerega et al. 2005b). Breadfruit remains most widely cultivated in Oceania, with the Caribbean region second. Breadfruit is considered an underutilized crop that has great potential in the future and its distribution throughout the tropics continues to expand. Outside of the tropics, it is often well known due to its role in the infamous mutiny aboard the *H.M.S. Bounty* in 1789.

The progenitor species of breadfruit, *A. camansi* (breadnut) and *A. mariannensis*, are both cultivated for their fruits and seeds in their native ranges and beyond. Breadnut is native to New Guinea and the Moluccas and probably naturalized in the Philippines. It is also cultivated for its seeds in parts of Southeast Asia, the Caribbean Islands, tropical Central and South America, and Africa. *Artocarpus mariannensis* is native to the Mariana Islands and Palau and has been introduced to other Micronesian and Polynesian islands.

Major Domestication Traits

The hundreds of named breadfruit cultivars found in Oceania were domesticated from either *A. camansi* alone or from both *A. camansi* and *A. mariannensis*. Selection in breadfruit appears to have focused on increased flesh content, at the expense of seeds (many cultivars are seedless), and through a decrease in the fruit core size. In addition, the fruit surface texture is smoother in the domesticate, making it easier for peeling (Jones et al. 2013). These characteristics may have been selected for since they make pit fermentation easier – a traditional way for Pacific Islanders to store food and ensure a predictable food supply. The change in seediness correlates with a change in propagation methods; the progenitor species are seed propagated, while breadfruit is predominantly vegetatively propagated with most of the seedless cultivars being sterile triploids. Seeded cultivars are most common in the southwestern Pacific Islands, while seedless cultivars are most common in Micronesia and the eastern islands of Polynesia. Virtually all breadfruit found elsewhere in the tropics is seedless. In addition to the loss of seeds, other changes occurred in the texture and color of the fruit flesh and surface, as well as in leaf shape, size, and leaf pubescence. To date, limited studies have been conducted on the change in nutritional content of breadfruit compared to its progenitor species (Jones et al. 2011b).

Timing and Tracking Domestication

Archaeological remains of breadfruit have been found on several islands throughout Oceania; however, available records are limited and a systematic study aimed at tracing the history of its domestication based on these data does not exist. Breadfruit is a significant part of the culture in Oceania, and there are numerous legends throughout the islands about its origins. Although the exact details differ, many of these stories in Polynesia describe the tree arising from the body of a god or man who willingly sacrificed himself in order to provide sustenance to a family or village during a time of famine. The similarities suggest that the stories may have been passed along with the breadfruit from island to island.

Genetic and morphological data from hundreds of breadfruit cultivars and the two progenitor species are now available and have begun to paint a picture of breadfruit origins and its path of human-mediated distribution throughout the islands of Oceania (Zerega et al. 2004). Breadfruit in Melanesia and Polynesia bear the genetic fingerprint of breadnut alone, while much of the breadfruit in Micronesia bears the fingerprint (and morphological characteristics) of both progenitor species. Considering these data in light of

Breadfruit: Origins and Development, Fig. 2 Distribution and proposed human-mediated migration of breadfruit and its relatives. The native range of *A. camansi* and *A. mariannensis* are shaded in gray. The range of domesticated breadfruit and hybrids and their level of seediness are indicated within the dotted lines. Arrows indicate general directions of human migrations and are simplified from actual migration routes. Times are estimates of Lapita migrations likely carrying breadfruit or its progenitors and are given in years before present (YBP) and come from Kirch (2000)∗ or McCoy et al. (2010)∗∗

what is known about human colonization of the islands helps explain this pattern (Fig. 2).

The Lapita were a seafaring people on the move out of Southeast Asia, and they quickly fanned eastward from northern New Guinea about 3,500 years ago, spreading through Melanesia and Polynesia bringing plants (like breadnut) with them. *Artocarpus* seeds remain viable for only a few weeks, so as the distances of voyages increased into the more remote and not yet colonized islands of Polynesia, vegetative propagation through root cuttings would have been the preferred method of transport – this is also true for many other important crops in Oceania which are vegetatively propagated, including *Colocasia esculenta* (taro), *Dioscorea spp*. (yams), and *Piper methysticum* (kava). Successive generations of vegetative propagation eventually gave rise to seedless triploid cultivars that were preferentially selected. Additionally, the genetic diversity and level of seediness of breadfruit decreases eastward from Melanesia into Polynesia with the progressive narrowing of the gene pool with subsequent migrations. Generally, the prominence of seedless cultivars increases as one travels from New Guinea eastward through Melanesia (where seeded cultivars are common) into western Polynesia (where few-seeded and seedless cultivars are prevalent) and into eastern Polynesia (where virtually all cultivars are seedless triploids). Finally, a long-distance migration from eastern Melanesia (possibly from Vanuatu or the Solomon Islands) into Micronesia brought *A. camansi*-derived breadfruit into the range of *A. mariannensis* where the two species hybridized, giving rise to a new suite of breadfruit diversity bearing the genetic fingerprints of both progenitor species.

Breasted, James Henry

Lindsay Ambridge
Ottawa, ON, Canada

Basic Biographical Information

James Henry Breasted (1865–1935) was an American Egyptologist best known for his work as a historian, philologist, and epigrapher and as the founder of the Oriental Institute at the University of Chicago. Born in 1865 in Rockford, Illinois, Breasted was from a family of modest means; his father was a hardware store owner and, later, a traveling salesman. Consequently, Breasted's path to academia was fraught with financial struggle. The need to support his family was a factor in the considerable amount of educational outreach work – from public lectures to popularizing books – that he accepted; as a result, he became one of the most widely known historians of his generation (Ambridge 2010; for examples of popular work, see Breasted 1908, 1916).

Between 1880 and 1890, Breasted studied at several institutions: Northwestern College in Naperville, IL, where he concentrated in Latin; the Chicago College of Pharmacy; and the Chicago Theological Seminary. After excelling in Hebrew at the seminary, he was encouraged to pursue graduate work in Semitic languages with William Rainey Harper at Yale University (Breasted 1943: 13–25; Abt 2011: 4–16). After a year of study at Yale, and with the encouragement of Harper, Breasted departed for Germany in order to obtain a doctorate in Egyptology, a field of study not yet well established in American academia. In 1891 he matriculated at the Humboldt University of Berlin (known at the time as Friedrich-Wilhelms-Universität) and studied for the next 3 years under Adolf Erman, one of the foremost Egyptologists in Germany. By the fall of 1894, Breasted had completed his doctorate with a dissertation on the sun hymns of the New Kingdom pharaoh Akhenaten; married Frances Hart, a fellow American expatriate living in Berlin; secured a position as assistant in Egyptology at the University of Chicago; and embarked on his first tour of Egypt (Breasted 1943: 33–40, 58–66; Abt 2011: 23–40). He would remain with the University of Chicago for the duration of his career.

Major Accomplishments

Breasted excelled in languages; among those that he commanded were German, French, Latin, Hebrew, Arabic, ancient Egyptian (including

Coptic), and Assyrian. With his educational background rooted in philology, he gradually pioneered new epigraphic methods of copying, recording, and photographing ancient inscriptions. Crucial to the development of his epigraphic methodologies were the years from 1894 to 1908, when he was granted several leaves of absence from the University of Chicago in order to conduct research abroad. From 1899 to 1901, he toured the major museums of Europe, where he photographed, transcribed, and translated all of the museums' historical inscriptions of ancient Egypt (Wilson 1936: 99; Breasted 1943: 103–15; Abt 2011: 75–8). This work contributed to Adolf Erman's Egyptian dictionary – the *Wörterbuch der ägyptischen Sprache* – and culminated in Breasted's own multivolume *Ancient Records of Egypt*, published in 1906. His first tour of Egypt occurred in the winter season of 1894/1895, during which he recorded inscriptions at major archaeological sites in the Nile valley north of Aswan. In the winter seasons of 1905/1906 and 1906/1907, he led expeditions through both Upper and Lower Nubia from Naga in the south to Beit el-Wali in the north, further refining his epigraphic methods (for photos of these expeditions, see Larson 2006).

In the years between 1908 and 1919, Breasted focused on teaching, writing, and administration; he was the chair of the University of Chicago's Department of Oriental Languages and Literatures as well as the director of the Haskell Oriental Museum (now the Oriental Institute Museum). The most notable publications from the first half of his career include his popular and widely read *A History of Egypt from the Earliest Times to the Persian Conquest* (1905); *Ancient Records of Egypt* (1906); *Development of Religion and Thought in Ancient Egypt* (1912); and *Ancient Times, a History of the Early World* (1916), a textbook written for high school students.

Ancient Times had a significant impact on the future of American Egyptology when the book received a favorable response from Frederick Gates, business advisor to John D. Rockefeller, Sr. and his son, John D. Rockefeller, Jr. Consequently, Breasted sought research funding from the Rockefeller Foundation and in 1919, John D. Rockefeller, Jr. committed to 5 years of financial support, enabling Breasted to found the Oriental Institute at the University of Chicago. The Institute's first project in 1919/1920, led by Breasted, was a 9-month reconnaissance survey throughout the Middle East, a region of the world undergoing profound changes in the aftermath of World War I. On this trip, Breasted's team evaluated such sites as Ur, Lagash, Babylon, Assur, Nineveh, and Khorsabad (Emberling 2010).

With continued funding from Rockefeller, Breasted established permanent field headquarters for the Oriental Institute in Luxor, Egypt. Named "Chicago House," the site still serves as the base for the Institute's ongoing Epigraphic Survey of Theban temples, a project initiated by Breasted in 1924. By 1928, Breasted secured a multimillion-dollar grant from the Rockefeller Foundation, resulting in a permanent endowment for the Oriental Institute and the construction of the Institute's research center, completed in 1931 (Abt 2011: 284–6, 345–9). Although Breasted did not identify himself as an archaeologist – he acknowledged the difference between the goals and methodologies of his epigraphic work and those of excavations run by such archaeologists as Flinders Petrie and George Reisner – in his capacity as director of the Oriental Institute he initiated excavations at such sites as Megiddo, Çatal Hüyük, Khorsabad, Tell Asmar, and Persepolis.

The heavy administrative duties of the Oriental Institute slowed Breasted's own research during the second half of his career. Two notable publications from this period are *The Edwin Smith Surgical Papyrus* (1930) and *The Dawn of Conscience* (1934). His wife, Frances, died in 1934; in June of 1935, he married his wife's younger sister, Imogen. The marriage was short-lived, however, as Breasted fell ill on the return journey from a tour of the Middle East in that same year. By the time his ship arrived in New York, Breasted had developed a streptococcal infection and he died on December 2, 1935, at the age of 70. He was survived by three children: Charles, James Henry, Jr., and Astrid.

British Isles: Medieval Archaeology

Tadhg O'Keeffe
School of Archaeology, University College Dublin, Dublin, Republic of Ireland

B

Introduction

As a geographic entity the British Isles refers to the two large northwest European islands of Great Britain (England, Scotland, and Wales) and Ireland and the smaller offshore islands which belong in their jurisdictions. The term is not popular in the Republic of Ireland, independent of British rule since 1922 and a republic since 1949, but, with attempts to re-brand the two islands as an Atlantic archipelago not having had much success, Irish commentators across a multiplicity of scholarly fields refer instead to "Britain and Ireland" (or "Ireland and Britain"). Historically, the "British Isles" is acceptable, however, and has no relationship with issues of modern sovereignty.

Definition

Traditionally, there are two problematic areas of definition, one of the discipline itself and one of the temporal boundaries and internal temporal subdivisions of the Middle Ages. These matter less to those medieval archaeologists (increasing in number) who engage directly with archaeological theory than they do to archaeologists of a more traditional, cultural-historical, persuasion, but they remain at the core of the discipline nonetheless.

Regarding the former, there are two ways of viewing Medieval Archaeology. One is period based: it is simply the study of the archaeological record of the Middle Ages and differs from prehistoric archaeology only insofar as a historical record provides clues to understanding and dating material remains. The second is sensitive to the particular epistemological challenges posed by a

written record alongside a material record and is conscious of the skills required to negotiate the historical record without feeling reliant on those skills. In many ways, this distinction between two types or conceptions of Medieval Archaeology parallels a similar distinction in the field of Historical Archaeology.

Regarding the second of the two problematic areas of definition, the debate as to the start and end dates of the Middle Ages is a slightly irrelevant one in that there was no understanding among medieval people that they were in the middle of anything. But the consensus now is that if a start date for the Middle Ages in the British Isles is required, the best option is to assign the collapse of the Roman Empire in the early fifth century and the near-simultaneous diffusion of Christianity from that Roman world into the "Celtic West," to the very end of the premedieval period. This brings the insular chronology into line with that of much of Continental Europe, especially western Europe and the Mediterranean lands. The watershed in England, southern Wales, and southern Scotland is marked specifically by the departure of Roman legions and, in eastern England, by the beginnings of Anglo-Saxon period, the latter a phenomenon that is still hotly debated. The transition from premedieval to medieval is less well defined in other parts of Britain, but the indigenous populations of these areas, speaking what are described by modern scholars as Celtic languages, would not have been unaffected by the presence of Roman culture and so would not have been unaffected by its ending, even if it took time for the cultural implications of the Roman departure to be absorbed. Ireland was not part of the Roman Empire, but the earliest documentation of Christianity dates from the early fifth century and specifically the sending by the pope of a bishop (Palladius) to minister to Christians (presumably Roman traders) resident on the island. A later though still fifth-century bishop, Patrick, is credited with the conversion of the people of Ireland, though other unnamed missionaries must have been involved and the process must have continued into the 500 s if not also the 600 s.

There is less consensus on the end date of the Middle Ages, mainly because moments or events which stand out as historically pivotal do not necessarily chime with shifts in worldviews or changes in material practice, the indicators that archaeologists use in periodizing. For archaeologists who like historical correlatives, the period of Henry VIII's reign (1509–1547) provides two key touchstones: his establishment of the Protestant Church in the 1530s and the dissolution of the monasteries between 1536 and 1541. Archaeologists who work more independently of historical narratives prefer to focus on the emergence of Renaissance culture or the shift from "feudalism," which is a hotly contested concept, to "capitalism," which is slightly less hotly contested (Gaimster and Stamper 1997; Gaimster and Gilchrist 2003). For these phenomena there is no fixed chronology and certainly none that can be applied to all parts of the British Isles. There is at least some agreement that, even in the most remote parts of the islands, the medieval period is over by the start of the seventeenth century.

Key Issues/Current Debates/Future Directions/Examples

Aspects of the medieval past on the two islands, whatever the chronological boundaries given to that past, have been the specific subject of archaeological investigations as we might understand them today since the early twentieth century (Gerrard 2003). Archaeological work of the 1800s, fitful with respect to the medieval heritage, is best regarded under the heading of "antiquarianism": conservation work on medieval monuments in Great Britain, for example, usually necessitated wall-chasing trenches, dug and emptied with little concern for data other than structural and material. Among the key works establishing the modern discipline was E.T. Leeds, *The Archaeology of the Anglo-Saxon Settlements* (1913), a work which, through opening up the potential of archaeological investigations to reveal the origins of the English people, laid the foundation for the especially enduring richness-of-tradition of Anglo-Saxon archaeological scholarship, a foundation built upon by the discovery of the Sutton Hoo Anglo-Saxon burial in 1939. There are no such benchmarks in Ireland until the publications of the excavations of a series of

early medieval sites by Hugh O'Neill Hencken of *The Harvard Mission to Ireland 1932–36*. To the preoccupation with Anglo-Saxon and Celtic archaeologies during the first decades of the last century was added a concern, mainly in the 1970s, for Viking Archaeology, the impetus being the urban excavations in York and Dublin. By that stage the discipline had its own dedicated society, the Society for Medieval Archaeology, founded in 1957, the journal of which, *Medieval Archaeology*, still generously offers a forum for pan-European investigations but is still largely comprised of papers on British themes. Research on the High Middle Ages, the period starting with the Norman invasion of England of 1066, followed by the Anglo-Norman spread into lowland Scotland and (especially) eastern Ireland in the twelfth century, was less systematically conducted, reflecting somewhat ironically the much greater diversity and volume of high-medieval archaeological material on the one hand and the availability of an historical record to provide an overarching interpretative framework on the other. That is not to say that there was no systematic research; on the contrary, projects like the excavations at Wharram Percy, and organizations such as the Medieval Pottery Research Group (founded in 1975), created a rich tradition. Works of synthesis only appeared late in the century (Clarke 1984; Barry 1987; Yeoman 1995), after the Society for Medieval Archaeology had celebrated its quarter-century anniversary with a volume of essays (Hinton 1983) which revealed a youthful discipline in thrall to historical narratives and, arguably, struggling to achieve some rapprochement with the New Archaeology (or processual archaeology, as we call it now).

The last quarter of the century has seen significant growth in Medieval Archaeology in these islands. The expansion of lectureships in British and (mainly in the 1990s) Irish universities puts it alongside longer-established areas on the educational curriculum. Medieval Archaeology remains a strongly cross-disciplinary pursuit in these islands, and most archaeologists possess a cognizance of the historical record and an ability to make sense of it without feeling enslaved by it. Traditional questions remain on the agenda – the origins of the English village and, by extension, the origins of Englishness itself; rural settlement in Scotland and Wales; and the fugitive archaeology if Gaelic-Irish communities in high medieval Ireland – but answers, while not definitive, are more advanced. More significantly, progress in "scientific archaeology" – the reconstruction of diet from skeletal remains and DNA analysis of human populations and remote sensing (such as LiDAR) on the other – has had a transformative impact on our understanding of medieval populations and their activities and, to the credit of practitioners, has been advanced with full cognizance of the importance of connecting "scientific" understandings to "cultural understandings." Moreover, there has been a parallel growth in awareness of the value of thinking theoretically beyond traditional culture-history (although it is markedly less advanced in Ireland, where even the New Archaeology was eschewed in the 1970s), than in the United Kingdom; comparison between the publication celebrating of the Society for Medieval Archaeology's half-century anniversary (Gilchrist and Reynolds 2009) and that of 25 years earlier shows the extent to which the subject has grown in recent years.

British Museum

Caroline Tully
School of Historical and Philosophical Studies, University of Melbourne, Parkville, VIC, Australia

Basic Information

Situated in Great Russell Street, London, the British Museum (http://www.britishmuseum.org/) was created by an Act of Parliament in 1753 and opened to the public in 1759. Governed by a board of 25 trustees in accordance with the British Museum Act of 1963 and the Museums and Galleries Act of 1992, the museum is a non-departmental public body, sponsored by the Department for Culture, Media and Sport. The museum's stated purpose is "to hold for the benefit and education of humanity a collection representative of world cultures and to ensure that the collection is housed in safety, conserved, curated, researched and exhibited" (British Museum n.d.).

The British Museum originated with the collection belonging to physician and naturalist, Sir Hans Sloane (1660–1753), which consisted of natural history specimens, ethnographic material, antiquities, jewelry, coins, medals, prints, and Orientalia. This was combined with a large library of manuscripts assembled by Sir Robert Cotton, and the Harleian Library, the manuscript collection of the earls of Oxford. Expanded in 1757 with the addition of King George II's donation of the old Royal Library, the museum thus originally mainly consisted of natural history specimens, books, and manuscripts. In 1772, the museum acquired its first collection of notable antiquities with the Greek vases belonging to Sir William Hamilton. In 1807, it created a specific Department of Antiquities which, in 1860, was divided into three: Greek and Roman Antiquities, Oriental Antiquities, and Coins and Medals. In the early 1880s, the museum divested itself of its Natural History collection, consequently making space for its expanding collection of antiquities. In 1997, the books and manuscripts making up the National Library were moved from the British Museum to their new home at St Pancras, and the Museum's circular Reading Room subsequently incorporated, in 2000, into the redesigned Great Court (Wilson 2002).

Today the Museum is made up of ten departments, primarily consisting of antiquities, which together contain eight million objects: The Department of Ancient Egypt and Sudan houses material from the Nile Valley, spanning the Predynastic Neolithic c.10,000 BCE to the Coptic Christian period in the twelfth century CE. It includes such famous objects as the colossal bust of Ramesses II, the Gayer Anderson cat, the Amarna tablets, and the Rosetta Stone. The Department of Greece and Rome houses Mediterranean antiquities dating from the Bronze Age to the fourth century CE and includes bronze sculpture, Greek vases, elements from the Mausoleum at Halicarnassus and the Temple of Artemis at Ephesus, and the controversial Elgin Marbles. The Department of the Middle East focuses upon the material culture of Mesopotamia, Iran, the Levant, Anatolia, Arabia, Central Asia, and the Caucasus from the Neolithic period to the present.

It contains objects such as Sumerian material from the royal cemetery at Ur, the Old-Babylonian "Queen of the Night" plaque, the Black Obelisk of Shalmaneser III, and the lion-hunt reliefs from the Assyrian palaces at Nimrud and Nineveh.

The museum's Department of Prehistory and Europe focuses on the Paleolithic and Neolithic periods, the Bronze and Iron Ages, Roman Britain, and the Medieval and Renaissance periods up to the present. It houses such objects as the seventh-century CE Sutton Hoo Anglo-Saxon ship burial and the Lewis Chessmen. It works in conjunction with the Department of Portable Antiquities and Treasure which coordinates the Portable Antiquities Scheme through which archaeological objects found by members of the public are recorded and which administers the Treasure Act 1996 on behalf of the UK Government. The Department of Asia contains material spanning the Neolithic c. 4000 BCE to the present and includes the Buddhist limestone reliefs from Amaravati. The Department of Africa, Oceania, and the Americas combines ethnographic, historical, archaeological, and contemporary material and includes the controversial Benin bronzes. The Department of Coins and Medals is concerned with the history of coinage from the seventh century BCE to the present. The Department of Prints and Drawings contains the National Collection of Western prints and drawings, dating from the fifteenth century to the present day, and the Department of Conservation and Scientific Research works with the other departments to conserve and study the collection.

Major Impact

The British Museum can claim to be the first national museum in the world. Its collection is among the largest and most extensive in existence and formed the basis of what later became the Natural History Museum which opened in 1881 and the British Library created in 1973. The museum has a long association with archaeological excavation, beginning with Charles Fellow's expedition to Xanthos in Asia Minor in 1840. It supported Austen Henry Layard's excavations in Assyria which resulted in the discovery of Ashurbanipal's great library of cuneiform tablets. The museum was also involved in the creation of the Egypt Exploration Fund in 1882. The museum maintains an active role in many national and international archaeological fieldwork projects. It encourages its staff to participate in excavation and fieldwork and is one of the chief British sources of funds for research excavation. The museum is also inextricably involved in the debate about the Return of Cultural Property, with the Elgin Marbles, the Rosetta Stone, and the Benin Bronzes as the most prominent among the contested objects in its collection (Wilson 2002).

The museum is the UK's most popular visitor attraction (FitzGerald 2012) and seeks to actively engage with the public. Museum facilities such as departmental study rooms and libraries are accessible to members of the public undertaking their own research. The museum collection is available online with a searchable database containing 2,335,338 records which represent over 4,000,000 objects, 1,018,471 of which are accompanied by one or more photographs. The British Museum Press publishes books relating to exhibitions and aspects of the collection, and the museum also has three online journals – *The British Museum Studies in Ancient Egypt and Sudan*, *British Museum Technical Research Bulletin*, and *Bronze Age Review*. The museum website also includes a blog containing regular posts by members of staff on recent news, exhibitions, acquisitions, aspects of the collection, and archaeological excavations. The museum works in partnership with universities to offer higher education courses, actively encourages visits by school groups, and holds family-focused events.

British Pioneers and Fieldwork Traditions

Timothy Darvill
Department of Archaeology, Anthropology and Forensic Science, Bournemouth University, Bournemouth, Dorset, UK

From its antiquarian origins, the development of field method in Britain reflects attempts by archaeologists to balance the merits of survey against excavation, research against rescue, and empiricism against theorized interpretation. While early methods lacked consistency, most were based on a modified form of empiricism known as inductivism: observations in the field gathered together to create interpretative statements (Marsden 1983). Richard Colt Hoare (1758–1838), excavator of more than 500 sites in the early 1800s, memorably summed up the position by declaring that "We speak from facts not theory" as the epigraph to *Ancient Wiltshire* published between 1812 and 1820. Importantly, a community of practice emerged to foster a network of amenity societies.

The late nineteenth century was a watershed in the development of archaeological fieldwork. Positivism strengthened as the preferred philosophy, suiting archaeology well by perpetuating distinctions between "facts" as things that could be observed and "laws" or "interpretations" as statements making sense of the facts. Maintaining the integrity of the facts therefore became important, and one of the main steps toward achieving this involved structuring investigation methods and recording systems. Leading this field was General Pitt Rivers (1827–1900) whose interests in social evolution carried through to developing a method of excavation that charted sequences of activity at particular sites. In practice this meant recording every object so it could be replaced accurately in its findspot through the use of plans and section drawings – essentially three-dimensional recording of finds. A generation later Mortimer Wheeler (1890–1976) added the need to record strata (every layer) three-dimensionally as well. To achieve this he developed an excavation method that still bears his name – the Wheeler System – in which the area of investigation was divided into squares with balks between. Each square was separately excavated, and the plans and four sections of each were carefully drawn (Wheeler 1954).

Continental methods of *open-area excavation* were meanwhile imported into Britain, notably by Gerhard Bersu (1889–1964) at Little Woodbury, Wiltshire, in 1938–1939. This approach to excavation and recording had far-reaching consequences after the Second World War, but even during the war, a small team of archaeologists led by W.F. Grimes (1905–1988) recorded sites in this way before they were destroyed by the construction of military installations. Noteworthy was Grimes' rigorous open-plan excavation of the

Burn Ground long barrow, Gloucestershire, in 1940–1941 where he planned every stone in the mound. After the war, rebuilding programs coupled with industrial expansion, agricultural extensification, urban regeneration, and infrastructure renewal created many opportunities for archaeological investigation. Subsequent changes in methodology can be gauged from five successive textbooks on the subject by Richard Atkinson (1946), John Coles (1972), Philip Barker (1977), Steve Roskams (2001), and Martin Carver (2009).

Operationally, work has expanded into hitherto under-investigated environments such as occupied towns, wetlands, uplands, agricultural land, and coastlands, often with rich rewards. Practically, there was much experimentation with the shape and size of excavation trenches, including uses of quadrant methods, *planum* systems, and large-scale open-area excavation taken from continental innovations. However in Britain attention remained focused on the removal of individual layers, or *contexts* as they became widely known, in the reverse stratigraphic order to deposition. Teasing apart complicated sequences, finding natural construction or erosional surfaces, positive and negative features, deposits and cuts, became a technical as well as an intellectual challenge (Hodder 1999). Finds were associated with contexts as the basic unit of recovery, and the application of archaeological site science promoted systematic sampling for ecofacts and artifacts down to microscopic levels as well as the recovery of environmental indicators and chemical characterization.

In field survey, the tradition based on the idea of cultural property and monuments promoted by Pitt Rivers was continued for much of the twentieth century by government-sponsored "Royal Commissions" which had the remit of recording everything visible on the surface (Crawford 1960). Aerial photography was adopted for archaeology immediately after World War 1 and exported to the countries of the then British Empire. The postwar period saw the development of "landscape archaeology," a set of more sophisticated and analytical approaches that focused on wide geographical areas and assumed that the land was regularly overwritten by successive generations to form a "palimpsest" (Darvill 2001). Aerial photography, remote sensing, ground surveys, place-name studies, and past cartography were among the many primary sources used to create landscape regression models – snapshots of a landscape as it might have been at a particular period. Uniquely, in England, where treasure hunting on private property remains legal, a new voluntary scheme has encouraged the reporting of objects found by metal detectorists. The *Portable Antiquities Scheme* has produced an immense harvest of reported finds, creating a rich geographical database of dated artifacts, the majority of metal.

From the 1960s representatives from museums, universities, local and national archaeological societies, local authorities, and the government agencies began working together to meet the needs of *rescue archaeology* in their locality. While the rescue of archaeological strata in Britain is not obligated by law, in 1990 its justification was embedded in Planning Policy Guidance Note 16 (=PPG16 *Archaeology and Planning*) for England, with similar statements for other parts of Britain. Periodically updated, most recently in 2012 as the *National Planning Policy Framework*, these remain the basis for the funding of archaeological intervention by the private sector. An excess of 4,000 investigations a year have been undertaken in England alone since 2000. This has coincided with a revolution in IT, resulting in innovative approaches to on-site data capture and the subsequent production and processing of plans, sections, photographs, and descriptive records. Compiled in *client reports*, these are presented to the commercial sponsors of the work in fulfillment of contract.

More than 90% of archaeological fieldwork in Britain is now prompted by planned commercial development. It comprises predetermination work, such as desk-based assessments, field evaluations, and Environmental Impact Assessments, and post-determination work that focuses on mitigating impact, implementing conservation measures, recording buildings, and investigating deposits faced with destruction through a range of techniques that include both trenching and open-area excavation. Conceptually, the

archaeological resource of the 1970s and 1980s, *heritage* as it was called in the 1990s, has now been redefined as *historic environment* assets. Large-scale projects remain common, including, for example, the high-speed railway line from London to the Channel Tunnel, Terminal 5 at London's Heathrow Airport, and the Hinkley Point C nuclear power station. But size is less important than quality. Since revisions to the planning system in 2012, and the gathering strength of "localism" as a political philosophy, integrating archaeology with local communities and using the knowledge generated to create public value have taken center stage.

From about 2006, economic instability and the global recession had various effects on archaeological fieldwork traditions in Britain. Initially, the profession scaled back in the face of lower demand for archaeological services (Aitchison 2010), although by 2017 had bounced back to earlier levels of activity. The respite in activity also allows the chance to take stock of achievements over the previous 20 years (Darvill et al. 2018): to rebalance the scope and aims of fieldwork, reconcile positivist and relativist approaches under the rubrics of creative science and community engagement, promote academic recognition and definitions of the discipline, and integrate opportunities offered by development-driven research with the power of problem-orientated research – in fact, a twenty-first century version of the agenda faced 300 years ago by the founders of Britain's fieldwork traditions.

British School at Athens

Robert K. Pitt
The British School at Athens, Athens, Greece

Basic Information

The British School at Athens is a research institute for Hellenic studies across all fields and periods. Situated in the center of Athens, the school consists of a hostel for resident scholars, an extensive library with map and archive collections, a small museum, and the Fitch Laboratory for science-based archaeology. At Knossos, the BSA maintains a residential field center and Stratigraphical Museum which form the base for its excavations and research in Crete. Work conducted by the school was published in the *Journal of Hellenic Studies* until the establishment of the first volume of the *Annual* for the 1894–1895 session. Each year since 1955, the school has produced a digest of all fieldwork in Greece, *Archaeology in Greece*,

jointly with the Hellenic Society and now supplemented online in a collaboration with the French school. The school's website is at www.bsa.ac.uk.

Foundation and Early History

As the discipline of archaeology rapidly developed in the nineteenth century, a number of countries established foreign schools in Greece. The first to open in Athens was the École française d'Athènes in 1846, followed by the Deutsches Archäologisches Institut in 1874, and in 1881 the American School of Classical Studies. The idea for a British institute in Athens was championed by Sir Richard Jebb, whose "Plea for a British Institute at Athens" in the *Fortnightly Review* in May 1883 provided the impetus for a public meeting held by the Prince of Wales, later King Edward VII, at Marlborough House in London, with guests including Lords Salisbury and Rosebery and the Prime Minister, William Gladstone. A committee was formed for the school which gathered donations toward the construction of a building in Athens.

During a visit to Athens in 1878, Jebb had contacted Charilaos Trikoupis, then foreign minister of Greece. In 1882, Trikoupis became prime minister and the following year offered a plot of land donated by the monastery of Petraki for the school on the slopes of Mt. Lykavittos. Opened in November 1886, the school building (now the Director's residence) was completed according to a design by the first Director, Francis Penrose, who had studied Athenian architecture for the Society of Dilettanti. Increased student numbers necessitated the building of a separate hostel at the lower end of the garden in 1897, which after three subsequent enlargements now comprises accommodations, offices, and common areas and is linked to the Penrose Library, built in 1904 and itself subsequently enlarged.

Financially, the school was reliant upon subscriptions and donations until Her Majesty's Treasury was persuaded to support the institution with an annual grant. Today the school continues to receive significant funding from the British government through the British Academy.

Major Impact

Archaeological Fieldwork

From its origins, the school was interested in a wide spectrum of fields: anthropology and ethnography, history, epigraphy, linguistics, art, and architecture. Among its archaeological fieldwork, the school has excavated widely in the Cyclades, Crete, Laconia, and Macedonia. One of the earliest major digs was at Phylakopi on Melos, begun in 1896, which began a long-standing focus for the school on the prehistory of Greece. Duncan Mackenzie's stratigraphical work here was advanced for its time, providing him with skills he would later bring to Knossos in 1900 as the deputy of Sir Arthur Evans.

In the early years of the twentieth century, the school began its long association with Sparta and its surrounding Laconian territory. Excavation began at Sparta in 1906, and investigations over a 100 years have uncovered the shrine of Athena Chalkioikos and the city's theater, the Sanctuary of Artemis Orthia, the Menelaion, Agios Stefanos, Kouphovouno, and Pavlopetri.

The school also maintains a long association with Mycenae. In 1920, the then Director of the school, Alan Wace, began working within the citadel as well as excavating the prehistoric cemetery outside it, investigating all nine tholos tombs in the surrounding area; his work was continued by Lord William Taylour in several seasons between 1960 and 1969; Wace's daughter, Elizabeth French (BSA Director, 1988–1994), has continued the school's work there in cooperation with the Greek Archaeological Service in the Mycenae survey.

Other important excavations carried out by the school include the following: the harbor and sanctuary site at Perachora in the Corinthia, conducted between 1930 and 1933 by the then Director Humfry Payne; work on the islands of Chios and Mytilene, including the 1930s excavations of Winifred Lamb at Kato Phana and Thermi, respectively; and at Lefkandi in Evia, where investigation of the settlement of Xeropolis began in 1964 under Mervyn Popham and Hugh Sackett, followed by discoveries in the cemeteries, including the remarkable Toumba building.

The BSA also has a strong tradition in archaeological survey from the broad regional surveys of Wace and Thompson in Thessaly and Macedonia and John Pendlebury on Crete to the pioneering intensive surveys of Melos by Colin Renfrew and John Cherry. In more recent years, large-scale field surveys have investigated Laconia, Boeotia, Kythera, and the Knossos valley, adding greatly to the methodological underpinning of this important field.

Crete

The school has a history of involvement in Crete beginning with the formation of the Cretan Exploration Fund in 1899, a joint venture between Sir Arthur Evans and the then Director D. G. Hogarth. Evans began digging the palace at Knossos in 1900, while Hogarth investigated the town, as well as the Dictaean Cave, one of the supposed birthplaces of Zeus. In 1901 and 1902, R. Carr Bosanquet excavated at the east Cretan site of Praisos, discovering inscriptions in the non-Greek language of Eteocretan; he later excavated the Minoan town of Palaikastro, where further excavations have continued since the 1960s.

Evans continued his work at Knossos for 21 years, with regular reports in the *Annual of the British School at Athens*. The spectacular excavations caught the imagination of the world in much the way that Schliemann's earlier excavations at Troy and the shaft graves at Mycenae had done. In 1926, Evans donated his entire Knossos estate to the school, including the palace, his own house (the Villa Ariadne), various other excavated areas, and outlying buildings. A Knossos curatorship was instituted, thus establishing a permanent BSA presence on site. In 1955, the school donated the bulk of the estate to the Greek state, retaining the Curator's house and a residential and study facility, and is responsible for the Stratigraphical Museum, where the bulk of recent excavation finds are housed.

BSA Collections

The BSA library covers all aspects of Hellenic studies, holding more than 70,000 books and over 1300 periodical titles with special emphasis on art, archaeology, epigraphy, archaeological sciences, Modern Greek, and Balkan history and society. The archives form the official repository for the records of the BSA, including documents from fieldwork projects, corporate papers, personal collections of BSA members, various historical documents associated with the early travelers to Greece, a photographic archive, and a unique collection of photographs and drawings from the Byzantine Research Fund. A museum houses a study collection of antiquities donated or excavated by the school and a sherd collection of survey pottery from across Greece. The core of the original library and antiquities collection were donated in 1899 by the executors of the Philhellene George Finlay (1799–1875), who first came to Greece in 1823 aged 24, became actively involved with the Greek struggle for independence with Lord Byron, and settled in Athens for the remainder of his life.

The Fitch Laboratory

Founded in 1974, the Mark and Ismene Fitch Laboratory promotes the integrated use of scientific methods and techniques in the archaeological study of material culture. Its research focus is on the study of ancient pottery and metals from Greece and the central and eastern Mediterranean employing optical microscopy and chemical analysis techniques. The Fitch houses reference collections of animal and fish bones, seeds, and pottery thin sections.

Brown Top Millet: Origins and Development

Eleanor Kingwell-Banham and Dorian Q. Fuller
Institute of Archaeology, University College London, London, UK

Basic Species Information

Brown top millet, which goes by the scientific name *Brachiaria ramosa* (L.) Stapf. or *Urochloa ramosa* (L.) R.D. Webster, is known locally as *pedda-sama* and *korne*, and has a limited cultivation largely confined to southern India. Domestic and wild/weedy forms of brown top millet are found in agricultural systems, often within the same field. It is used as both a human food crop and fodder. Outside of India, it is grown in some parts of the USA as a fodder crop, largely to provide food for game birds, and was introduced from India around 1915. Although its distribution is highly relict today, restricted to parts remote parts of Andhra Pradesh, Karnataka, and Tamil Nadu states in southern India (Kimata et al. 2000), it appears to have been a major staple crop in the late prehistory of the wider region of the Deccan (Fuller et al. 2004).

In several parts of India, brown top millet is known by local names which translate to "illegal wife of little millet [*Panicum sumatrense*]," reflecting its tendency to grow within fields of little millet as a mimic weed (Sakamoto 1987). Brown top millet can grow with either a compact or open panicle and can have either shattering or indehiscent spikelets. The domestic form, however, tends to act like other domestic cereals and is both compact and partially indehiscent (Kimata et al. 2000). Where brown top millet occurs as a weed of other millet fields, it is usually treated as an insurance crop.

Major Domestication Traits

Brown top millet is particularly tolerant of drought and is well adapted to semiarid areas. It grows well at altitudes of 2000–2500 m, with 75–150 cm annual rainfall (Roecklein and Leung 1987). Cultivation is more common in the dry areas of Karnataka and Andhra Pradesh at lower elevations, South India, than in other parts of the world. Brown top millet grows and matures over around 90 days, a shorter time than several other millets including pearl millet (*Pannisetum glaucum*). It is usually grown as a single crop and not incorporated into mixed field systems. Harvesting in the early morning while the dew is still on the crop reduces the amount of grain lost through panicle shattering. Shattering (dehiscence) is reduced compared to the wild forms, but it is still partially shattering. The crop tends to be cut at the base, then winnowed, dehusked, and polished. Because it is semi-shattering, its grains can become dislodged just by being dried which reduces the need to thresh, although it requires dehusking like most other millets. Straw and chaff is often used as animal fodder; however, the grain is reserved for human consumption and is said to be tastier than rice. Brown top millet tends to be ground into flour and used to make flat breads (*roti, dosa*) or polished and boiled to make gruel (*anna, kheer*). Some of these foods are used in religious rituals, which may partly account for its persistence in cultivation (Kimata et al. 2000).

The identification of brown top millet grain and spikelets can be difficult due to its similarity to *Setaria italica* (Fig. 1). Although the panicle is distinct from *Setaria* by being looser and non-

Brown Top Millet: Origins and Development, Fig. 1 Drawing of *Brachiatia ramosa* panicles, spikelet, hulled and de-hulled grains, showing the rugose husk patterns of the lemma and palea. SEM images of lemma and palea patterns inset

bristly, the grains themselves are very similar. Grains are ovate to round and have a long embryo, roughly two thirds to three fourths of the length of the grain. They tend to be smaller than *Setaria italica* and squatter in cross section. The surface of well-preserved grains can be used for identification as these have a distinctive undulating pattern, although this again has similarities to *S. italica* (Fuller et al. 2004). The husk has a fine beaded and rugose pattern, which again has some resemblance to that of *Setaria* spp., but it is somewhat coarser than *S. italica* and finer than *S. verticillata*.

Timing and Tracking Domestication

The domestication of brown top millet probably occurred in South India, in the Deccan, and it spread during prehistory outward to other parts of India (Fig. 2). Charred grains identified as "*Brachiaria ramosa* type" have been recovered from most Neolithic South Indian sites where systematic archaeobotanical work has occurred. On these sites brown top millet has a high ubiquity and relative frequency. Dating the time of domestication is complicated by the fact that little archaeobotanic work has been carried out on early Neolithic or preceramic period (Mesolithic sites); however, the evidence suggests that this crop, along with other South Indian crops (i.e., *Macrotyloma uniflorum, Vigna radiata* and *Setaria verticillata*), developed from indigenous wild populations around the beginning of the third millennium BCE (Fuller 2006). During this period, local millets and legumes were incorporated into an agro-pastoral system, part of the ash-mound culture of the southern Neolithic of India, which employed both mobile cattle pastoralism and small-scale crop cultivation. Brown top millet spread out from the Deccan to Tamil Nadu in the south (Cooke et al. 2005) and Gujarat in the north by the end of the second millennium BCE. Small quantities of the grain have also been found from Chalcolithic (late second–early first millennium BCE) sites in Odisha (Orissa) in the east and some sites in the Ganges plains (Harvey 2006), however, the number of grains recovered does not suggest cultivation and may represent wild plants.

Brown Top Millet: Origins and Development, Fig. 2 Distribution map of archaeological finds of *Brachiaria ramosa* in relation to the Southern Indian Neolithic and modern cultivation of this crop

Over time, brown top millet has seen reduced use, although it was still present at the site of Paithan in Maharashtra up to the seventh century CE. Its gradual reduction in use can be attributed to displacement by alternative, more productive millets, including the African millets (*Sorghum bicolor*, *Eleusine coracana*), as well as foxtail millet (*Setaria italica*) that probably contributed to this. Today brown top millet is a relict cultivar but one with some important ritual uses.

Buckley, Kristal

Kristal Buckley
Deakin University, Melbourne, VIC, Australia

Basic Biographical Information

Kristal Buckley (AM) received her B.A. (Hons) from Australian National University in 1980. She holds a Graduate Diploma in Social Sciences from the University of New England (1985). Her Master of Public Policy degree was conferred in 1998 from the University of Melbourne.

Major Accomplishments

Kristal Buckley (AM) has served as an International Vice-President of ICOMOS since 2005, and has been an active contributor to many aspects of the work of the International Executive Committee including the ICOMOS World Heritage programme and Scientific Council, and with ICOMOS members and National Committees in the Asia-Pacific region. Trained in archaeology, anthropology, and public policy, Kristal Buckley is a lecturer in Cultural Heritage at Deakin University's Cultural Heritage Centre for Asia and the Pacific in Melbourne, Australia. She has worked as a heritage consultant in private practice and in government. She served as a full member of the Heritage Council of Victoria for 9 years, and has represented cultural heritage professionals at advocacy and advisory forums at the national level. Her work in Australia has included Indigenous and non-Indigenous heritage projects, policy, and management, with an emphasis on community involvement. She is a member of the ICOMOS ISC for Intangible Cultural Heritage. She has also worked as an advisor to governments in environmental policy – particularly in relation to sustainability and climate change and was recently appointed as Member of the Order of Australia for significant service to conservation and the environment, particularly in the area of cultural heritage, and to education.

Buckwheat: Origins and Development

Alison Weisskopf and Dorian Q. Fuller
Institute of Archaeology, University College London, London, UK

Basic Species Information

Buckwheat, including common buckwheat (*Fagopyrum esculentum* Moench.) and tartary

buckwheat or bitter buckwheat (*Fagopyrum tartaricum* (L.) Gaertn.), is one of only three important non-grass starchy grain crops, or pseudo-cereals, the others being grain amaranth (*Amaranthus* sp.) and various chenopods, such as Andean quinoa (*Chenopodium quinoa*). An important crop of marginal lands, buckwheat, is grown in nearly every country that cultivates grain crops and is usually consumed locally (Campbell 1976), but it is especially important in colder regions of high altitude or high latitude in Asia. It is mainly grown for the starchy white endosperm of its seeds which produces buckwheat flour used for pancakes and *blini*, and soba noodles (Japan). The whole hulled seeds are used as breakfast food and to thicken soups. Dehulled grains, milled to remove the pericarp, are used in *kasha*, a traditional Russian dish. Buckwheat has a level of around 9% protein, has 330–350 kcal per 100 g, and does not contain gluten. Buckwheat is grown as a green manure, is a common animal feed, and is also a major honey-producing plant (Campbell 1997; Van Wyk 2005).

The name *Fagopyrum* is derived from the Greek *fagos*, beech and *pyrum*, wheat. The common name, buckwheat, is from *Buchswein*, German for beech wheat on account of the triangular seeds that look like small beech nuts. Other common names include: *Sarrisin* (French); *grano saraceno*, *fagopiro* (Italian); *kyoubaku*, *soba* (Japanese); *trigo-sarraceno* (Portuguese); *grano sarraceno* (Spanish). Many of the common names, *Sarrasin*, *gran saraceno*, *trigo-sarraceno*, *grano sarraceno*, mean Saracen grain, demonstrating buckwheat's eastern origins, although it actually comes from much further east (van Wyk 2005). For Chinese, it is *qiao-mai*, and in Hindi *kotu*. Less widely cultivated is *F. tartaricum*, the Siberian, Indian, Tartary, or bitter buckwheat, which is especially important for its height tolerance in the Himalayas and Tibet. Another species occasionally cultivated in northeastern India and southwest China is *Fagopyrum emarginatum*.

Major Domestication Traits

Buckwheat is an annual plant with a succulent hollow angular stem, swollen nodes, and alternate triangular acute leaves 5–10-cm long (Fig. 1). It has terminal and axillary white pink red or yellow flowers, which produce small dry fruits (achenes), which are gray brown to black. These may be technically classified as a diclesium, and after removing the outer dry bracts, yield an edible reddish nutlet with white starchy endosperm (Fig. 1) (Stevens 1912). Comparison of domesticated and wild species suggests selection for annual habit, non shattering inflorescence, low seed dormancy, and increased seed size, much as in cereal crops (Fuller and Allaby 2009). Common buckwheat is normally self-incompatible,

Buckwheat: Origins and Development, Fig. 1 Images of buckwheat, showing the growth habit of cultivated buckwheat (*Fagopyrum esculentum*), the fruit and nutlet with cross sections, with a comparison of the nutlet and cross section of tartary buckwheat (*Fagopyrum esculentum*)

Buckwheat: Origins and Development, Fig. 2 Map showing distribution of wild *Fagopyrum tartaricum*, the subzone of wild *F. esculentum*, and archaeological and palynological sites that have produced early evidence for buckwheat

and tartary buckwheat readily self-pollinates (Campbell 1976). Plants grow to full height of around 1 m in about 6 weeks and the seeds ripen at around 10–11 weeks. This short growth cycle allows for cultivation in highly marginal habitats and short high elevation summers, although buckwheat has low yield compared to other grain crops. Buckwheat extends easily to above 3000 m under cultivation, and is grown alongside barley at the highest elevations. Tartary buckwheat is even better adapted to the highest elevations, up to c. 4000 m.

Buckwheat originates in the Tibetan plateau or nearby mountains of Yunnan, southwest China. There 16 wild species of *Fagopyrum*, all focused on the Himalayan and southwest China region (Campbell 1997). The wild progenitor of *F. esculentum* is thought to be *F. esculentum* ssp. *ancestralis*, which has a limited distribution in the mountains of western Yunnan and Sichuan (Fig. 2). It has a narrow distribution, growing at 1000–1500 m above sea level in barren rocky habitats with poor soils along the Jinsha River, Yunnan, and the Yalong River in Sichuan never entering cultivated fields (Ohnishi 2004). Wild tartary buckwheat, *F. tartaricum* ssp. *potanini*, is more widespread on the Tibetan plateau (Fig. 2; see Campbell 1997; Ohnishi 2004).

Timing and Tracking Domestication

Archaeological remains are rare, and much evidence for its spread comes from pollen appearances in palaeoenvironmental sequences. These data have been recently assessed by Boivin et al. (2012), with particular reference to the dispersal westward toward Europe. Pollen finds in three areas of China from c. 4500 BP suggest that cultivation began by the early Third Millennium BCE at the latest (Fig. 2). Finds include from the Liaohe river basin in northeast China after c. 2200 BCE, Xishanping in Gansu to the northwest, where pollen could be as early as c. 2500 BCE, although there are some stratigraphically inconsistent AMS dates might be only about 1000 BCE (Li et al. 2007). Additional evidence comes from the Lower Yangzte, suggesting some buckwheat cultivation in the hills south of

the Yangzte as early as 4500 BP. Finds from Japan all occur after 4000 BP, with an early reported nutlet from Hamanasuno in north Japan being shown to be intrusive by AMS dating. A few macro-remains finds can be placed in the First Millennium BCE, including from central Nepal and at Haimenkou, Yunnan (Boivin et al. 2012). Later evidence from Nepal is that of Kohla, a site at over 3000 m from the twelfth to thirteenth century CE.

The westward dispersal across Eurasia is particularly controversial. Some have suggested that pollen evidence indicates Neolithic presence in Europe by the Fifth Millennium BCE (Janik 2002), but a critical review of the archaeological and historical evidence would suggest buckwheat reaches the eastern margins of Europe not earlier than about 4000 years ago, and central and western Europe only in the late Middle Ages, c. CE 1300 (Boivin et al. 2012). Despite the importance of this crop for allowing expansion of human settlement into some of the most marginal and cold environments, there is still little known of its early cultivation and dispersal.

Buikstra, Jane E.

Sonia Guillén
Centro Mallqui, Lima, Peru

Basic Biographical Information

Jane Ellen Buikstra (1945–) is one of the most influential and outstanding American anthropologists in the field. Her scientific and academic work has had global influence. She obtained her Bachelor's degree in Anthropology from DePauw University in Indiana in 1967, and her Master's (1969) and Doctorate (1972) degrees from the University of Chicago.

She had faculty positions at Northwestern University, University of Chicago, and University of New Mexico. She was Research Associate at the Field Museum of Natural History, the Museum of the American Indian, the University of Florida, and the National Museum of Natural History. Buikstra is currently a Regent's Professor of

Bioarchaeology and Director of the Center for Bioarchaeological Research of the School of Human Evolution and Social Change at Arizona State University, Tempe, Arizona.

She has a long association with the Center for American Archaeology where she is President of the Board of Directors. This institution has had a very important role in the development of bioarchaeology. Associated field seasons in Kampsville, Illinois, have included training and educational programs associated with continuous research in numerous archaeological sites including Koster and Mound House as part of contract work with the Central Illinois Expressway program.

Buikstra defined and promoted the field of bioarchaeology, a specialty of archaeological research focused in the integration of information recovered from human remains in the reconstruction of ancient lifeways. This approach has redefined the role of physical anthropologists and archaeologists working with mortuary remains. The specialist trained in the study and recovery of human biological evidence is involved from the recovery fieldwork up to a range of specialized studies including chemistry, diet, growth and health, genetics, and paleodemography. In the area of paleopathology, Buikstra is recognized for promoting the use of rigorous differential diagnosis in the evaluation of lesions in human remains (e.g., Buikstra and Roberts 2012).

Buikstra has received numerous awards and distinctions in recognition of her accomplishments. She was elected a member of the National Academy of Sciences in 1987; was the Harold H. Swift Distinguished Service Professor at the University of Chicago, the Leslie Spier distinguished Professor of Anthropology at the University of New Mexico, and the George E. Burch Fellow in Theoretic Medicine and Affiliated Sciences at the Smithsonian Institution; and received the Pomerance Award for Scientific Contributions to Archaeology from the Archaeology Institute of America.

Buikstra's work has focused on the study of prehistoric skeletal collections incorporating cultural and biological data to evaluate evolutionary change, growth, health, and development. Her studies include important contributions to more fully understanding mortuary behavior, demography, paleopathology, biological distance, and paleonutrition, among numerous topics related to the adaptation and history of prehistoric societies. Buikstra has published numerous articles, books, reviews, and nontechnical publications (see Further Reading section below).

Her publications and academic work show an intense dedication to the promotion of science, the field of anthropology, and the status of women. Buikstra has mentored students and scientists from all over the world, including Indonesia, Australia, Peru, Chile, Argentina, Spain, China, and Ireland, and has contributed to academic programs and professional meetings. Buikstra and her collaborators have significantly influenced aspects of the scientific work involving the recovery, study, and conservation of human remains, both ancient and modern.

Major Accomplishments

Buikstra has received numerous grants to support her research including from the National Science Foundation, the National Institute of Health, Wenner-Gren Foundation, National Geographic Society, National Endowment for the Humanities, the Illinois Department of Transportation, and the Illinois Historic Preservation Agency, among others. She has directed and participated in bioarchaeological projects in most parts of the world, numerous projects in the North American Midwest, as well as in the Canadian Arctic, Argentina, Brazil and Peru, as well as in Spain, Israel, Turkey, and Honduras.

Buikstra has actively participated in professional associations and committees. She has served in different capacities including the top positions in the American Anthropological

Association, the American Association for the Advancement of Science, the American Association of Physical Anthropologists, the American Board of Forensic Anthropology, and the Society for American Archaeology.

Buikstra has also contributed as editor of several professional journals such as *American Anthropologist*, the *Journal of the American Association of Physical Anthropologists*, *Evolutionary Anthropology*, the *International Journal of Osteoarchaeology*, *International Journal of Paleopathology*, the *Journal of Forensic Sciences*, and the *Journal of Anthropological Research*, *Chungara*, of the University of Tarapaca in Chile. She has participated, in and promoted research groups that have proposed standards for the analysis of ancient human remains, the evolution of infectious diseases such as tuberculosis, and research and ethical aspects of the fields of forensic and biological anthropology and archaeology.

The ongoing career of Jane Buikstra is characterized by excellence in science reflected in her numerous publications and academic work and her strong commitment to teaching and professional development which has outreached to different parts of the globe.

Building Biographies

Jana Rogasch
Jana Anvari, Institut für Ur- und Frühgeschichte, Universität zu Köln, Köln, Germany

Introduction

Developing a biography of a building can be an important way of obtaining information about the activities and beliefs of past societies. The term "building biography" was first used in historical studies, where the approach is different from that of archaeology. In the historical tradition, the house is studied more as the frame around which a family or other social group or institution is investigated, as a case study to gain inside into social conditions of a certain period in a certain area (Russell Ellis et al. 1985; Dakers 1993; Silver 1994; Zaknic 2004; Alexander 2008). Such studies incorporate non-architectural evidence, such as photos and written records made during the lifetime of the building. As these forms of evidence are not available in much archaeological research, an archaeological building biography must focus on evidence from the architectural body itself.

The archaeological building biography was developed from the biographical study of artifacts, a concept influenced by anthropological theory that perceives artifacts as objects with a life history, from which conclusions can be drawn about the human society that produced them and used them. While the term "building biography" is used explicitly only in some archaeological publications (Gerritsen 1999a; Rogasch 2012), the underlying concept is employed in many more.

Definition

A building biography interprets architecture by focusing on the sequences of human activities and decisions that went into creating a building, using a building, and abandoning a building, part of a building, or a group of buildings. It is an interpretative model based on which research questions can be developed, and appropriate methods of analysis can be chosen to answer them. The aim is to reach an interpretation of larger processes in past societies from a detailed study of human activities that are preserved in the architectural record.

Key Issues/Current Debates/Future Directions/Examples

The key assumption of the biographical approach is that when people interact with "things," the people, the things, and the relationships between them are altered during and by this interaction. Among the many possible different paths each of these intertwined biographies could theoretically take, only certain biographical possibilities are actually realized, and this range of acceptable options is determined by the given social context (Kopytoff 1986: 66, 68; Bernbeck 2008: 52).

The possible archaeological application of the concept was first explicitly outlined in a book edited by Appadurai (1986) in his book *The Social Life of Things*, and subsequently embraced by many archaeologists and used on a broad range to research questions (for overviews, see *World Archaeology Journal* 31(2) 1999; Skibo and Schiffer 2008). A number of terms are used to capture the target of these studies: "life" or "social life" (Appadurai 1986; Horne 1994: 170; Tringham 1995: 98), "use life" (Banning and Byrd 1987: 321; Tringham 1995; Tringham and Stevanović 2012), "life history" (Appadurai 1986: 41; Tringham 1995: 97; Gerritsen 1999a: 82; Holtorf 2002; Tringham and Stevanović 2012), "life course" or "life cycle" (Horne 1994: 185; Boivin 2000: 367; Matthews 2005), "development cycle" (Banning and Byrd 1987: 309, 321; Boivin 2000: 367), "career" (Appadurai 1986: 41;

Horne 1994: 185) and "biography" (Appadurai 1986: 17; Tringham 1995: 97; Gerritsen 1999a: "biography" and "cultural biography").

Archaeologists concerned with research into architecture soon adopted the biographical approach. Through building biographies, archaeologists have reconstructed household-related processes (Banning and Byrd 1987: 321; Tringham 1995: 97; Gerritsen 1999a; Boivin 2000; Matthews 2005; Tringham and Stevanović 2012); rituals and beliefs (Banning and Byrd 1987: 322; Gerritsen 1999a); issues of ownership (Banning and Byrd 1987: 323; Gerritsen 1999a: 95); the interplay between architecture and the surrounding landscape (Tringham 1995: 97; Gerritsen 1999a: 93); community construction (Düring 2005; Rogasch 2012); and mobility practices (Gerritsen 1999a; Bernbeck 2008; Rogasch 2012).

The following beneficial results of the biographical approach to architecture have been pointed out by researchers using it, and their reviewers:

1. *Comprehensiveness*: A biography considers the entire life of a building, from pre-construction to post-abandonment, and thus fully appreciates all available data and interpretational possibilities.

   Traditionally architectural studies focus on what they perceive as the main or intended use phase of the building (Tringham 1995: 81). However, recent archaeological research has demonstrated the interpretational potential of knowledge employed and choices made during and even before a construction process (Gerritsen 1999b: 109; Love 2012) and behavior during house abandonment (Gerritsen 1999a: 83–5, 87–91; Matthews 2005; Rogasch 2012).
2. *Resolution*: As a biography renders importance to the small scale, it fosters meticulous analysis and the recognition of important differences in the biographies of different architectural units, whose interpretation can lead to a clearer and more realistic picture of societies. This counteracts the tendency in architecture studies to brush over inconsistencies in search for a greater truth (Tringham 1995: 95; Vellinga 1999: 98–99): in terms of temporal resolution, that often results in a more fine-grained relative sequence of events even in the absence of absolute dating.
3. *Dynamism*: Such high-resolution sequences facilitate the identification of dynamic processes happening around a building (Vellinga 1999; Nevett 1999), which reflects complex realities observed in modern societies (Horne 1994; Carsten and Hugh-Jones 1995) better than the traditional archaeological thinking of seeing architecture as static (Tringham 1995: 65; Vellinga 1999: 98). The term "biography," as drawing comparisons with human life histories, points out the unplanned nature of life ways that resulted in biographies which could not have been foreseen when the life started.
4. *Workability*: It is possible and relevant to apply the biographical approach on different scales: the biography of one wall, one post, one room, one building (Rogasch 2012), a settlement (Bernbeck 2008), up to the biography of a landscape with built and unbuilt spaces (Vermeulen 2001; Pollard and Reynolds 2002; Gerritsen 2003; Darvill 2006; Roymans et al. 2009). It can therefore be applied to all evidence at hand, even if only fragments of buildings have been excavated.

For a *critical evaluation* of the biographical approach in general, see Holtorf's (2002) work who states that the concept is too loosely defined and used rather arbitrarily ("intellectual virus") to solve very different kinds of problems (also remarked by Nevett 1999: 102).

Nevett (1999: 102; similarly Vellinga 1999) criticizes that biographical studies often simply collect a lot of facts without actually subjecting them to systematic analysis, thus resulting in "lack of explanatory force of the biographical approach" (Gerritsen 1999b: 109) or even the perception that "the application of the biographic approach to the study of late prehistoric houses is ultimately inadequate" (Vellinga 1999: 101).

This shows again that a building biography is a model of interpretation that does not replace analysis. The biography has to be filled with detailed

evidence generated through traditional tools of architecture research such as stratigraphical research or studies of building materials and constructions techniques. The number of very recent publications in the list of references below demonstrates that the biographical study of architecture is constantly being refined and will develop further in the near future.

Buildings Archaeology

Kate Giles
Department of Archaeology, University of York, York, UK

Introduction

This entry seeks to outline the context and current practice of buildings archaeology. It focuses primarily on the UK but sets current practice here within the wider context of Northern Europe, the USA, and Canada. The entry commences with a definition of the discipline, during which its emergence in the late twentieth century as a subdiscipline of archaeology is charted. Key issues and current debates in the practice of buildings archaeology are then considered. These include its internationally significant role in the documentation and preservation of global cultural heritage, the development of recording methods and techniques, and interpretative issues such as the application of stratigraphic analysis to standing buildings, the impact of theoretical paradigm shifts on the discipline, and the potential of new virtual and visualization technologies to transform both methodological and interpretative approaches in the future.

Definition

"Buildings' archaeology" can be defined as the application of the archaeological principles of systematic recording, analysis, and interpretation to "above ground archaeology" or standing buildings. In many countries, buildings' archaeology has emerged from well-established traditions of researching and analyzing buildings within disciplines such as art and architectural history. Indeed, the development of the discipline often provoked anxiety and hostility from specialists within these fields. However, in the UK, a distinctive approach to recording buildings also emerged in the 1980s out of the specific context of "rescue archaeology." Here, buildings' archaeology rapidly became associated with the application of "metrically accurate" recording methodologies and "stratigraphic" principles of analysis to the phasing and interpretation of buildings. During the 1990s and early part of the twenty-first century, the emergence of buildings' archaeology has coincided with, and informed, approaches to the "documentation" and preservation of cultural heritage. Throughout this period, the interpretation of buildings has also been informed and enhanced by critical engagement with developments in contemporary archaeological theory. While these trends are most evident in the approaches followed in the UK, they have much in common with the well-established German tradition of "*bauforschung*" or "*stadtbaugeschicte*," which form part of both commercial practice and many archaeology curricula (Grossman 2001), with the Swedish and Danish practice of buildings' archaeology, building history and "documentation hermeneutics" (Haedersdal 1999–2000), and Belgian building recording (Mignot and de Meulenmeester 2003).

Historical Background

Buildings archaeology in the UK traces its origins to the emergence of a systematic and scientific approach to the observation and recording of buildings by early Antiquarians associated with the Society of Antiquaries of London, founded in 1707. During the nineteenth century, architectural history emerged as a self-conscious specialism, particularly in the field of ecclesiastical buildings, where the analysis of past examples of Gothic architecture was linked both to the desire to develop systematic typologies of the style and to its use as a source for contemporary architectural designs within the Oxford and Cambridge movements.

It was only in the later part of the twentieth century, however, that the discipline of buildings' archaeology really emerged in the UK. Throughout the 1970s, groups of like-minded archaeologists and architectural historians began to develop what became known as "church archaeology": a multidisciplinary approach to excavating, recording, and researching all aspects of church sites, buildings, fittings and fixtures, and

burials. Techniques were informed by the contemporary development of "rescue" archaeology, where large-scale open-area excavations at sites such as Coppergate (York) and The Brooks (Winchester) shed important light on the below-ground remains of medieval buildings and provided a model for the integrated historical and archaeological analysis of medieval structures (Carver 2009). Rescue archaeology also led to rare examples of the systematic excavation and recording of a pair of medieval and later town houses along the city wall at Shrewsbury. Gradually, as traditional industries declined and development pressures increased in the 1980s and 1990s, larger numbers of industrial structures also formed the focus for archaeological recording of both buildings and the evidence of industrial processes which had occurred within them.

Gradually, the significance of historic buildings as part of the archaeological resource began to be accepted in the UK. In 1979, the Ancient Monuments and Archaeological Areas Act provided statutory protection for those buildings which had been designated scheduled ancient monuments, while in 1990, listed buildings were also protected under the Listed Buildings and Conservation Areas Act, although parish churches and cathedrals are subject to separate legislation under the Ecclesiastical Exemption (revised 2010) and Care of Cathedrals Measure (revised 2011).

Key Issues/Current Debates

From tentative origins within church, rescue and industrial archaeology, buildings' archaeology emerged gradually in the 1990s as a distinctive subdiscipline within the field. However, its development sparked strong responses from other disciplines, particularly architectural history. Church archaeology had demonstrated how the methods of below-ground recording, particularly the idea of a "total" recovery of data destroyed during the excavation process, could be transferred to the recording of standing buildings. However, doubts were raised about the problems inherent in the "misapplication to building recording of the practices of dirt archaeology." Buildings archaeology was largely a nondestructive recording process, associated only rarely with the creation of "preservation by record" where a building was to be completely destroyed. However, building recording methods did seek to replace art historical approaches to recording buildings, which were considered to be partial and subjective, with a more objective and totalizing approach to recording.

At the heart of this debate lay a fundamental difference of opinion about what constituted authority within the disciplines of architectural history and archaeology in the UK. A consensus began to emerge, first that the idea of the "total" record was a chimera, and, second that from the moment a decision was taken to record a building, choices were made about what – and what not – to record. The subjectivity of the recording process itself was acknowledged (Grenville and Morris 1992: 301), and the importance of recording and interpretation being driven by clear research questions and a thorough understanding of building types was also emphasized. Today, one of the most important legacies of this debate for buildings' archaeology is the idea that although it is impossible – and perhaps undesirable – to be objective in the recording of buildings, it is still important to document the process in a systematic and accessible manner, which can be interrogated and reinterpreted by subsequent scholars.

As early as the 1990s, the value of recording as "an essential prerequisite and accompaniment to the repair and conservation process" was emphasized by buildings' archaeologists and conservation practitioners in the UK. The role of buildings' archaeology was argued to be not simply that of facilitating alteration but also informing decision-making. This might involve weighing up possible development proposals against the perceived value or significance of a building, and academics argued strongly that a necessary precursor of conferring value on a building was scholarly "understanding." These debates had important implications for the relationship between buildings' archaeology and conservation.

Example 1

A landmark volume, *Buildings Archaeology*: *Applications in Practice* (Wood 1994), brought together academics and practitioners from across the commercial and public sector, including English Heritage (EH), the RCHME, the National Trust, National Parks, and archaeological units in a series of thematic essays and case studies demonstrating the value of buildings' archaeology within the heritage and conservation sector. "Extensive" survey examples featured in the volume included a survey of an entire building type – "bastles" – by the Northumberland National Park and a survey of three nineteenth-century industrial Welsh "housing stocks," both of which were designed to target recording and conservation resources effectively. More "intensive" survey examples included targeted recording for limited alterations in English Heritage's secular buildings and the detailed recording by the Lancaster Unit of major conservation works at the scheduled monument Furness Abbey in advance of major restoration works. Two further case studies involved intensive survey prior to demolition of vernacular buildings and dismantling prior to re-erection at Kellington church.

Another example of this role of buildings' archaeology is Pearson and Meeson's (2001) edited volume, *Vernacular Buildings in a Changing World*: *Understanding*, *Recording and Conservation*. Many of the case studies in this volume were concerned to emphasize the significance and the potential of the vernacular architecture resource and to highlight the particular vulnerability of vernacular, often unlisted buildings, to insensitive alteration and development without adequate archaeological recording. Through a series of case studies, the volume reflects critically on tensions within the system: the lack of effective use by Conservation Officers of PPG15; the misconception that "conservation" was synonymous with resistance to change; and the lack of dialogue between buildings' archaeology and other professions, such as conservation architects, surveyors, structural engineers, and planners.

Throughout the latter part of the twentieth century, debates about the interrelationship of legislation and planning guidance, academic research frameworks, and commercial practice have continued to dominate the discourse of buildings' archaeology. Of particular significance in recent years has been the way in which research-based building recording has been placed at the heart of heritage practice and planning guidance, largely as a result of the widespread dissemination of international heritage conventions and charters such as Athens, Venice, Burra, and Faro. The global cultural and economic impact of developments in international conservation charters and conventions has recently been explored by Letellier and The Getty Institute's (2012) two-volume publication, volume 2 of which consists of a series of international conservation-led recording case studies (see also ICOMOS 1990). In the UK, the high-level philosophical concepts such as "significance" and "value" defined in these charters have become embedded in national policy guidelines, such as EH's (2008) *Conservation Principles*. *Informed Conservation* (Clark 2001) has also had particular resonance for buildings' archaeology, coining the acronym CoBRA (Conservation-Based Research and Analysis) to describe "the research, analysis, survey and investigation necessary to understand the significance of a building and its landscape and thus inform decisions about repair, alteration, use and management."

Example 2

Informed Conservation not only explained the value of understanding as the basis of defining significance but also discussed the appropriate levels of information required for different kinds of conservation projects, the forms of strategic document used and the specific analytical techniques available. Throughout, examples drawn from the work of EH's own metric survey team, such as the eighteenth-century town house, Danson House, Bexleyheath, were used to illustrate CoBRA in practice. Although CoBRA has never really made it into the common parlance of buildings' archaeologists, its principles have become widely accepted. Other useful published examples include Acton Court, Burlington House, and Stowe. In Spring 2009, an entire edition of EH's *Conservation Bulletin* provided examples of

"Conservation Principles in Practice," and Heaton (2007) and Neale (2010) provide a similarly useful surveys of case studies in which attitudes to the "restoration" of historic buildings have been transformed by initiatives such as *Conservation Principles*. At the time of writing, major changes are occurring in the UK's system of planning policy and guidance which are already having an impact on the role of building recording in the heritage and conservation process (Morrice 2011; Heaton 2012).

The Practice of Building Recording: Guidelines and Principles

Early reactions against the idea of total and objective recording methodologies in the UK gradually informed the development of principles and guidelines governing a "selective" approach to recording. This was enhanced by the increasing recognition that archaeological projects needed to justify a level of recording appropriate not only to the significance of the building but also the practical and financial constraints imposed by the commercial sector. Buildings archaeology in the UK tends to draw on two main guidance documents. EH's (2006) *Understanding Historic Buildings*: *A Guide to Good Practice* provides "clear practical guidance on the ways in which the wealth of historical evidence embodied in buildings can be gathered and disseminated for the lasting benefit and enjoyment of all." At the heart of the guidance is the definition of four "levels of recording" (where 1 is the most basic and 4 the most complex form of record) described in relation to three forms of record: written, drawn, and photographic. A table within the guidance maps the "circumstance" and "principle need" of recording against the four levels and forms of record. Similar, but subtly different, commercial priorities can be seen in the professional guidance of the UK's Institute of Field Archaeologists' *Standard and Guidance for the Archaeological Investigation and Recording of Standing Buildings or Structures* (2008). Once again, the need for archaeological building investigation and recording to be driven by a written specification or project design, in which appropriate levels of survey, accuracy, and the forms of reports are identified, is emphasized.

Understanding Historic Buildings emphasizes that its guidance is not intended to be prescriptive or definitive and acknowledges that different levels of recording may be required by different user groups, while different levels might be adopted within a single project or across a single site. Nevertheless, they provide a standard which is widely used by those commissioning and delivering building recording in the UK. Although neither of these documents provide explicit guidance on recording or interpretative methods, they do acknowledge technological advances are reflected in both documents, with sections on digital photography and digital archiving. However, both also emphasize the importance of historical research and the use of documentary sources, maps, and pictorial sources in researching and interpreting buildings. This contrasts with the methodology of buildings' archaeology outlined in the UK's principle textbook on the subject, where the use of documentary sources is relegated deliberately to Chap. 12 on the grounds that "The archaeology of buildings is really about the study of the evidence of the buildings themselves" and that undertaking documentary research prior to survey and interpretation can, "at the risk of sounding priggish, affect the purity of the purely archaeological analysis" (Morriss 2000: 165)!

Guidance on the practice of recording buildings can be found in a variety of sources. Morriss' (2000) volume provides basic guidance on hand survey, but one of the most useful step-by-step guides to historic building survey methods is that of Swallow et al.'s (2004). The volume provides a factual description of different survey methods but also reflects critically on their potential and limitations. It also provides a series of case studies which reflect on the interrelationship of selective recording principles and the choice of particular recording methods. This "toolbox" approach to guiding practitioners through choices of survey methods and case studies is also evident in EH's (2003) *Measured and Drawn* and in the second volume of Letellier and The Getty Institute's (2012) recent publication, with which English Heritage were closely involved. Useful individual

articles on particular techniques can also be found on the building conservation directory website: http://www.buildingconservation.com/articles/.

As well as guidance on survey methods, UK buildings' archaeology has also sought to establish standardized conventions relating to the visual outputs of building survey methods. Early guidance on the artistic conventions and production of standardized plans, sections, and elevations was also provided by the Association of Archaeological Illustrators and Surveyors (1995). Specific guidance on the use of CAD has also been produced (English Heritage 1998 and the Archaeology Data Service's 'CAD Guide to Good Practice': (http://ads.ahds.ac.uk/project/goodguides/cad/)).

Currently, there is considerable debate within buildings' archaeology in the UK about the relationship between the increasingly technological aspects of building survey, such as laser scanning and the analysis and interpretation of buildings. Some practitioners have argued that laser scanning offers a new, more objective, and "total" method of recording historic buildings. However, interestingly, projects such as Heritage3D (http://www.heritage3d.org/) have also recognized the current limitations of such technologies and emphasized the need for laser scanning to be selected on the same grounds as alternative recording techniques, namely, its ability and suitability to answer the research questions, or problems being posed.

Another current debate concerns visualization and the use of virtual reality models. Projects such as the historical theater modeling project, Theatron (www.theatron.co.uk), have demonstrated the potential of virtual reality technologies to generate visually pleasing computer graphics designed to evoke the visual experience of now-lost buildings. However, they have also raised questions about the extent to which "a" virtual model can inadvertently close down alternative and multiple interpretations of the same evidence. Heritage technologies can not only mask the process of recording but also "gap" between recording and subsequent scholarly interpretation. Increasingly, digital heritage practitioners have called for the development of a more critical approach to the use of computer reconstructions. This has resulted in the development in the UK of the "London Charter for the Computer-Based Visualisation of Cultural Heritage" initiative (www.thelondoncharter.org; Beacham et al. 2006). The London Charter encourages greater "transparency" in the creation and use of models through the publication of the "paradata" on which they are based.

Example 3

The Guild Chapel, Stratford-upon-Avon (Warwickshire), is a recent example of an integrated buildings' archaeology and virtual modeling research project (Giles et al. 2012). The chapel is an internationally significant late fifteenth-century building built by the Guild of the Holy Cross and Hugh Clopton, a guild member, merchant, and former Lord Mayor of London. The project sought to use a virtual model to reconstruct the chapel's original decorative scheme of wall paintings, which were partially destroyed at the Reformation but which came to light during restoration works in the nineteenth and twentieth centuries, when they were drawn by a series of Antiquarians. A metric survey of the chapel was used as a basis for a digital model. However, rather than seeking to reconstruct "the" appearance of the Guild Chapel, the model and its accompanying text was used explicitly to present the "paradata" of the wall paintings by layering different Antiquarian drawings and descriptions of the same images over each other, so that their similarities and differences can be compared directly by the user him/herself. In this way, the project seeks to remind the user of the "gaps" between the reality of the past and the interpretative processes of recording and representation discussed above.

One issue that greatly dominated the emergence of UK buildings' archaeology, but which no longer seems current, is the use of stratigraphic analysis in the interpretation of historic buildings (Grenville and Morris 1992: 301). Early buildings archaeologists maintained that stratigraphic recording provided a more systematic and reliable form of record than the fluid and partial records made by other disciplines. From the outset,

however, it was acknowledged that there were profound differences between the unconsolidated contexts of below-ground archaeology and the consolidated structures encountered within buildings, particularly with regard to the principle of superimposition and the definition of stratigraphic contexts.

Example 4

The most cogent discussion of these issues to date has been by Jones (2000), analysis of the ceiling over and partitioning of a medieval "Cruck Cottage," Cuppenham (Hampshire). Jones argues that stratigraphic units must be defined by the investigator in relation to the purpose and level of the record. At Cruck Cottage, context numbers were given not only to individual roof timbers but also to evidence of human activity such as "smoke blackening" to illuminate the process of "closure" in vernacular buildings. Jones' work also demonstrates how the systematic use of stratigraphic terms such as "cut" and "fill" or "abutment" provides a much clearer way of describing relationships within and between contexts than the traditionally ambiguous concept of the "building break" used more commonly in architectural history.

Early enthusiasm for the application of stratigraphic analysis to buildings encouraged the development within organizations such as the Central Archaeology Service at English Heritage of "recording manuals" and pro formas for the recording of "built structures" and "timber structures." However, skeptics of the stratigraphic approach have tended to question the value of such time-consuming recording methods, which, in presenting all information as being of equal value, "fail to guide the user to that which is significant." In Morriss' (2000: 154–5) volume, while the importance of the principle of analyzing the relationship between contexts is acknowledged, it is argued that the use of colored phase drawings is far easier and more effective method of interpretation than the creation of context sheets and Harris matrices. Over the past ten years, the detailed application of stratigraphic analysis to standing buildings, the use of pro formas and production of site matrices, seems to have become less common in both academic and commercial practice. However, rather than representing its abandonment of stratigraphic analysis, it can be argued that this represents the maturity of the discipline. The key significance of stratigraphic analysis for buildings' archaeology was that it represents "an intellectual framework which can be used to organize the different sources of evidence used to interpret a building." While the *principles* and *terminology* of stratigraphic analysis have been widely adopted and used in buildings' archaeology, it appears that they have been combined highly effectively with conventional and traditional ways of communicating and presenting such analysis – in the form of written descriptions, phased drawings, and reconstructions.

Theory and Buildings Archaeology

Alongside its function within the cultural heritage process, buildings' archaeology has also continued to explore theoretical approaches to the research and interpretation of historic buildings (Hicks and Horning 2006). Although early approaches to the interpretation of vernacular and industrial buildings tended to be very descriptive and functionalist, gradually buildings' archaeologists began to embrace structuralist and contextualist approaches such as the idea of "generative grammars," borrowed from historical archaeology in the US, and spatial analysis techniques such as space syntax and "isovist" or viewshed analysis (Locock 1994). As postmodern, or "post-processual," theoretical approaches began to impact the discipline, and buildings' archaeologists began to eschew the kinds of totalising narratives which these studies often produced and to focus rather on the complexity of the material evidence and the diversity of historical interpretations which could emerge from detailed building analysis (see Reynolds 2009). Current studies are particularly interested in the potential of applying "biographical" approaches to the study both of the individual occupants of buildings and the material biographies or histories of buildings themselves and of developing more phenomenological or experiential approaches to the theoretical interpretation of buildings. More

broadly, UK archaeologists have extended their remit to include the study of buildings across the historical period, including polite houses and gardens, institutional architecture, industrial buildings, and contemporary buildings.

International Perspectives and Future Directions

In 2012, the role of building recording, documentation and information management as being at the heart of cultural heritage and resource management appears to be recognized internationally. It is embedded in the charters and policies of ICOMOS and in European and US legislation and practice. The value of research-informed conservation for understanding and conserving high-profile, internationally significant buildings and much humbler, regionally and nationally significant structures is also acknowledged. The potential of building recording methodologies to be extended to wider cultural landscapes, and to inform structural and condition surveys, has also been demonstrated and recognized. The gradual acceptance of the methodology across the heritage profession has resulted in dialogue and information exchange, rather than the interdisciplinary hostility and protectionism which characterized its early days. New technologies are also being harnessed to enhance the presentation and interpretation of research. As building recording is gradually embedded in academic curricula, a new generation of professionals is emerging internationally, with a greater understanding of its benefits and potential to enhancing understanding and inform conservation.

The greatest threat to the future development of the field is the economic crisis currently affecting most of Europe and North America. The loss of conservation professionals at both local, regional, and national level due to budget cuts, and the absence of dialogue between practitioners, is a major source for concern in the UK. The desire to boost the construction industry by removing or waiving existing legislation and policy also threatens the role of recording in the planning and development process in many countries, regions, and localities. Commercial units are under greater pressure than ever to deliver rapid results for minimum cost. Moreover, leading organizations, such as English Heritage in the UK and Parks Canada in North America, have experienced drastic budget cuts to units involved not only in recording but also in setting standards and monitoring their application within the profession. Only time will tell how the discipline emerges from this latest challenge, but it seems likely that academics and professionals will need to collaborate more than ever if we are to ensure that building recording continues to inform the understanding, conservation, and management of historic buildings and places into the twenty-first century.

Buildings, Archaeological Study of

Jason Wood
Heritage Consultancy Services, Lancaster, UK

Introduction

The study of buildings has always formed a significant part of archaeological endeavor. In Britain, research, illustration, and publication began to mount through the first half of the nineteenth century, not least through the national work of John Britton and Robert Willis and their regional contemporaries. These early students of historic buildings applied archaeological standards of draftsmanship and subsequent dissection, phasing, and analyses that permitted logical insights about dating, periodization, and typology. Indeed, Willis used the term "archaeology" to describe his recording techniques and their application at several English cathedrals. He knew the value of demonstrating structural and dating arguments through making proper records, and his work remains as valid today as it ever was. Of course, succeeding generations would set new standards and devise new procedural models, but Willis stands close to the start of the archaeological tradition that requires accurate measurement and drawing before an analysis is undertaken.

B

Key Issues/Current Debates/Future Directions/Examples

Research and Understanding

For Willis, and the subsequent researchers that he inspired, it was enough to demonstrate the academic benefits that accrued from the study of buildings. The notion of "pure" research for its own sake, simply to find out, may be unfashionable these days, but it is still alive. In this age of public accountability, however, academic curiosity and challenge may not be enough to secure the necessary financial or legislative support. Other benefits, such as opportunities for innovation and community engagement, must be demonstrated. Today, the study of buildings needs to be set within a wider intellectual context, and the archaeologist must ensure that research programs are carefully considered and coordinated with others in similar fields before work begins.

In recent years, the role of the archaeologist and the application of modern archaeological practice have been extended to inform the conservation and management of historic buildings. This is based on the firm belief that it is not possible to conserve or manage a building without first understanding its history. There is a need to know how and why a building was constructed, how the spaces within a building and between buildings were altered and used through time, what survives of the building and what has been lost, as well as any association with individuals and events. In this way, the study of buildings is inevitably drawn down the path of research – albeit research directed toward a practical outcome. This understanding is documented through the process of making analytical records.

The ultimate aim of understanding buildings is to define their *significance*, so that the historical asset may be retained and enhanced. In particular,

it is essential to recognize those aspects that make buildings important enough to justify the necessary conservation time and effort. It is impossible to say, for example, whether or not a particular roof structure should undergo extensive repair or be renewed until it is known what date that roof structure is and how important it is relative to comparable roof structures elsewhere. To put it in a single word, the importance of a building or group of buildings will need to be "*characterized*" and to gain credibility that characterization must be well documented.

Having characterized a building, the knowledge gained can then be used to address any sensitive management problems. This may lead to more intensive study to inform particular conservation or development proposals. Clearly not all buildings need to be studied in the same detail: different circumstances will demand different responses. The scope and level of documentation need to be economically tailored to particular conditions and will be dependent on a number of factors, such as the type and complexity of the building and the nature and scale of proposed works. Consideration should carefully be given to the appropriate kinds of analytical recording in each case. For instance, further research will be especially important for elaborate works programs on multiphase buildings where a greater understanding of the structural and material performance of the fabric is required to avoid damage and allow for appropriate preservation. Where, for example, it is necessary to deconstruct the timber frame of a building to repair decay, or where partial demolition of its masonry to remove rusting metal cramps cannot be avoided, it will be important to prepare precise records. For the dismantling of buildings for re-erection elsewhere, for example, in a museum, very detailed three-dimensional recording and numbering of all components will be required, in order to recreate the disposition and assembly of as much of the original fabric as practicable.

In such situations, the role of the archaeologist, often working in close partnerships with other disciplines, needs to be properly integrated with the project direction and monitoring team, usually under the leadership of the project architect. The most satisfactory projects will be those which, from the earliest possible stage, work with and take into account the skills and experience of a wide variety of specialists. As well as archaeologists, these may include architectural historians, structural engineers, materials specialists, and others (Fig. 1).

It should be noted that as a part of an historic building conservation or development project, the work of an archaeologist differs significantly from that associated with conventional archaeological fieldwork, in that the data can form a vital part of

Buildings, Archaeological Study of, Fig. 1 The major repair project at Ightham Mote, Kent (UK), undertaken on behalf of the National Trust, had the benefit throughout of an archaeologist working alongside the architect and contractor to inform the process and record what was discovered. (Photo: Jason Wood)

the subsequent works specification. Scaled drawings and photographs often provide the essential basis for detailed works proposals and consent applications. Such records may also be used for issuing instructions to building contractors. The need for accuracy and legibility are therefore paramount.

Techniques for Studying Buildings

Documentary research is important to establish the architectural and historical interest of a building and to elucidate the evidence for its history and development. This can be achieved in a number of ways. Most research should start with the obvious sources – the relevant statutory designation, a survey of standard reference works and existing secondary sources on both the individual building and of that class of building in general. Local authority record systems and record offices are often a good source of information, as well as national records and specialist archives. It is advisable not to restrict research to locally available material, as in many cases, crucial information will lie in national collections and may have been overlooked in the past.

In general, work should concentrate initially on the sources most likely to reveal evidence for the history of the fabric of the building, such as maps, plans, photographs, and other historic images. Most studies will benefit from a map regression exercise. This involves gathering copies of all relevant maps, starting with the most recent and working back through the whole sequence of every period. Topographical or other drawings, published views, and photographs are especially useful. Their collation can be time consuming, but the effort is not often wasted as these images frequently shed light on the original context and tell much about a building's function and pattern of alterations. Beyond these sources is a whole range of information including title deeds, taxation lists, and rate books, which can all be helpful to construct a simple chronology of ownership and tenancy.

Oral history has an important role to play in the study of buildings. People who have direct experience of a building's use and adaptation in the recent past may present opportunities to gather supporting evidence for changes in form or function. For example, the redevelopment of industrial buildings can benefit from contact with former employees resulting in a greater understanding of any surviving plant and its significance, informing decisions on retention or disposal. Defining significance is now a process that increasingly goes beyond expert values to encompass the wider community and to embrace public history. Capturing peoples' views and attitudes about buildings that are significant to them can be illuminating. A crucial aim must be to encourage people to tell their own stories, to share their personal and often "unofficial" history, and to explore further the forces that link these memories to specific buildings.

Fabric Survey and Analysis

Historical research alone is not sufficient: there must always be some degree of engagement with the fabric of the building. Drawings are an indispensable part of studying buildings. These can be produced using a variety of different survey methodologies, equipment, and related software packages:

Hand-measured survey involves the use of tape measures, plumb bobs, frames, and surveyor's levels.

Instrument-based survey involves the use of total station theodolite control, consisting of a closed-traverse run around and through a building, followed by trigonometric intersection of suitably observed points on a façade, or electronic distance meter tacheometry utilizing microprisms for cross sections through complex enclosed structures.

Photographic-based survey (often used in conjunction with hand-measured and instrument-based control) includes

Rectified photography, consisting of single photographs or a mosaic of overlapping photographs taken using large- or medium-format cameras aligned square to the object

Photogrammetry, based on stereophotography taken using metric cameras

Laser-based survey using terrestrial laser scanners. These record three-dimensional positions at a predetermined resolution over a chosen area, generating thousands of high-accuracy coordinates. The coordinates are stored as a series of XYZ measurements which visually constitute a point

Buildings, Archaeological Study of, Fig. 2 Laser scanning carried out by the University of Birmingham at Chedworth Roman Villa, Gloucestershire (UK), on behalf of the National Trust. (Photo: Jason Wood)

cloud that represents the geometric form of the building being scanned in three dimensions. Laser scanners also operate in complete darkness and are therefore unaffected by varying light levels, unlike more traditional recording methods (Fig. 2).

The resulting drawings are usually provided as a set of scaled plans, sections, elevations, and details (Fig. 3):

Plans: The requirement may include basement, ground and upper level floor plans, including plans of ceilings, vaults, and roof structures, showing relevant external and internal detail and features. The location of all sections and elevations should be identified. Plans are the fundamental product to which all other material can be related.

Buildings, Archaeological Study of, Fig. 3 Plans, elevations, and sections of the timber-framed stable block at Abbey Farmstead, Faversham, Kent (UK), recorded in advance of repair and refurbishment works. (Drawing: Lancaster University Archaeological Unit; courtesy of Oxford Archaeology and Swale Borough Council)

Sections: The requirement may include sections corresponding to the bay divisions or axes through the relevant parts of a building. These should normally define the principal wall plane and also include detail through adjacent openings and voids such as windows, doors, passageways, and smaller features such as putlog holes and beam sockets, as well as roof and floor detail. The height locations of all plans should be identified.

Elevations: The requirement may include external and internal elevations of the relevant parts of a building, depicting architectural features with associated detail (Fig. 4). Walls adjoining

Buildings, Archaeological Study of, Fig. 4 An elevation drawing of the church tower of St. George of England, Toddington, Bedfordshire (UK). Recording and analysis provided accurate base level information about the nature and historical development of the fabric to inform the repair program. (Drawing: Network Archaeology Ltd.; courtesy of Toddington PCC)

Buildings, Archaeological Study of, Fig. 5 An annotated ground plan showing suggested periods and phases of part of Whalley Abbey, Lancashire (UK). (Drawing: Lloyd Evans Prichard)

elevations should be depicted in section. The height locations of all plans should be identified.

Details: The requirement may include separate plans, sections, and elevations of representative openings and architectural features, with exploded views to supplement the two-dimensional record where appropriate (for example, carpentry joints), and representative architectural, decorative, and ornamental details, both loose and in situ (molding profiles, inscriptions, setting-out lines, tooling, nail positions, masons' and carpenters' marks, graffiti, etc.).

It is not possible, however, to understand an historic building on the basis of record drawings alone. Close analysis of the fabric will be required to establish the relative chronology of the building and its structural phases:

Analytical records: The requirement may include annotating the plans, sections, and elevations to depict boundaries between different types of building material (stone, brick, tile, wood, metal, glass, etc.); surface finishes (mortar, render, plaster, daub, paint, industrial lining, etc.); building periods, phases of construction and repair; constructional detail (wall alignments and thicknesses, bonding patterns, blockings, putlog holes, beam sockets, chase scars, butt joints, building lifts, work-gang breaks, fittings, etc.); occupational detail (wear marks, blackened timbers, industrial residues, etc.); and evidence for abandonment or demolition (robbing, salvaging, fire damage, etc.).

Interpretation records: The requirement may include plans, sections, and elevations depicting outline reconstruction of the principal elements and features, for each of the periods identified. Output may be presented as an annotated plane (Fig. 5) or three-dimensional or cutaway projection (Fig. 6).

Intervention records: "As-built" records, showing the extent of conservation or development works, should depict areas of rebuilding,

Buildings, Archaeological Study of, Fig. 6 A cutaway reconstruction drawing of the church at Furness Abbey, Cumbria (UK). (Drawing: David P Cooper)

rebedding, repointing, grouting, new fabric insertions, etc. "As-built" records are particularly important where a component or structure is dismantled, repaired, and then reassembled.

General photographic recording of the external and internal appearance of the significant parts of the building should be undertaken. Close-up photography will also often be required for architectural details.

Finally, detailed physical or chemical analysis of certain building materials, surface finishes, or residues can often provide essential corroborative information including technological and supplementary dating evidence.

Bulgaria: Maritime Cultural Heritage Management

Marina Vladimirova
State University of Library Studies and Information Technologies, Sofia, Bulgaria

Introduction

The Bulgarian Black Sea aquatory and its coastline reveal to us their extraordinary richness of cultural and historical heritage of national and world importance, whereas the locals keep the century knowledge of intangible traditional maritime culture. This huge volume of archaeological, historical and cultural, tangible and intangible, movable and unmovable heritage has been described and analyzed in detail in the scientific literature. However, the biggest part of it is still unknown for the broader audience. It is only kept in the memory of the locals, in the museums' storages, and in the exposition halls, which are not always able to represent it appropriately enough in order to provoke the public to get acquainted with it and to take an active part in its protection. At the same time, if the potential of the Bulgarian maritime cultural heritage is used effectively and with care for the heritage, this will ensure its preservation, will bring it closer to the general public, engaging local people, and thus guaranteeing the sustainable development of the Bulgarian Black Sea region. An effective approach for management and socialization of this heritage is needed in order the above measures to be achieved. However, some studies and publications have been developed lately. They provide guidance for possible successful approaches of management and socialization of this heritage, analyzing their potential outcomes. The management of Bulgarian maritime cultural heritage covers the maritime historical and archaeological artifacts from the Bulgarian Black Sea coastline and water area, and the traditional maritime culture.

Definition

The maritime cultural and historical heritage represents the tangible and intangible forms of expression with cultural, historical, and/or archaeological character, influenced by the proximity of the sea, and expressed in the material and spiritual culture of the coastal societies. It includes, but is not limited to, underwater cultural heritage; coastal fortresses; archaeological remains of the communities, who inhabit the region; ports and navigation structures; maritime landscapes; traditional maritime cultural, etc.

The Bulgarian maritime cultural and historical heritage as part of the world cultural heritage redounds to building identity, and it is crucial for the shared sense of community. Although, it is limited and nonrenewable resource, when managed effectively and rationally, it will play a significant role in the scientific studies, the tourism, and the sustainability development of the Bulgarian Black Sea region. It should be highlighted that in order the maritime cultural heritage to be socialized and managed, first and foremost, all requirements for its protection, preservation, and conservation must be met. Only then, all other management approaches for popularization and reaching the public, who will be the active part in maritime cultural heritage protection, can be applied successfully.

Part of the maritime cultural and historical remains that deserve to be managed and socialized are the submerged pile settlements. The study of the submerged settlements brings information about the economic life and socioeconomic

Bulgaria: Maritime Cultural Heritage Management, Fig. 1 Location of the submerged pile settlements in Varna and Beloslav Lakes as per Mikhail Lazarov (Лазаров 2009, 16–19)

Bulgaria: Maritime Cultural Heritage Management, Fig. 2 Reconstruction of stone anchors (Димитров и др. 1982, 446). From left to right: 1. stone weight with a grove; 2. stone anchor with a single hole; 3. stone anchor with two holes ("Thracian" anchor); 4. stone anchor with three holes (composite anchor or classic stone anchor)

structure of the communities inhabiting them. Fully or partially excavated submerged settlements in Bulgarian Black Sea water include (Лазаров 2009): 14 pile settlements (or 13 as in one case it can be assumed that it is one settlement developed in two different historical periods) in the Varna and Beloslav Lakes from the Eneolithic and Early Bronze Age (Fig. 1, p. 9); Late Eneolithic and Early Bronze Age settlement from the water area of the port of Sozopol; anonymous commercial-settlement-emporium in Vromos Bay from Antiquity; Thracian pile settlement from the Early Bronze Age in the Urdoviza peninsula's aquatory; and a settlement in the Ropotamo river estuary, which testifies habitation of this territory with interruptions from the 4th century BC to the Ottoman period. Relation between these settlements and other objects from the Turkish and Georgian coast has not been established yet (Angelova and Draganov 2003, 20).

Another extremely interesting group of objects from the Bulgarian sea aquatory are the stone anchors (Fig. 2, p. 10). Bulgaria is the country with the richest collection of stone anchors. The most acceptable period for stone anchors dating is the wide range of the II millennium BC (Лазаров 2009). The petrographic analysis of 150 stone anchors from Bulgarian Black Sea aquatory showed that 139 are made of stones/rocks from the Bulgarian region. Part of the anchors (around 16%) are made of rocks, which are not typical for the Western Black Sea region (Лазаров 2009). The huge amount of stone anchors, especially in the waters off the Bulgarian Black Sea coast, is indisputable proof of early Thracian seafaring

(Фол 2009, 58). The affiliation of the stone anchors found along the Bulgarian Black Sea coast to local and not Mediterranean species does not exclude the possibility these anchors to mark Bronze Age trade routes (Frost 1982, 280–289). The idea of early Thracian seafaring is supported by Porozhanov (Порожанов 2012, 253–254), too, and by the results from the excavation of the submerged settlements located in Varna and Beloslav Lakes, which demonstrate already developed fishery that requires vessels. The anchors that mark places for forced mooring are from different periods: anchors with wholes from the Bronze age, through stone and lead stocks, till the Late Roman and Early Byzantium iron anchors. The discovery of such anchorages provides the opportunity to draw conclusions for the typology of the lost anchors, and additionally, which sea routes were followed, during which period and with what type of ships (Frost 1982, 280–289).

According to Kalin Porozhanov (Порожанов 1984, 9), the seafaring in Ancient Thrace was caused by mining and metallurgy, because between XVI and VII century BC, the presence of copper, tin, lead, and iron is essential for the production of tools of labor and weapons that are vital for the survival and subsistence of the locals. Mikhail Lazarov (Лазаров 2009, 54–55) also supported the opinion that for the transfer of metal in Ancient times, the sea routes were used. In addition, the gold and copper mining earliest for Europe documented in Thrace was spread via the sea "routes" (Порожанов 2012, 253). Therefore, maybe it is not a coincidence that the oldest golden artifacts in the world are dated back in the Chalcolithic period and are excavated in the Varna Chalcolite necropolis located in a close proximity to Varna Lake.

The shipwrecks are the other group of objects that deserves to be mentioned. Some of the oldest vessels found in our waters are the so-called single-tree-trunk-boats some of which very well preserved. One of these boats was found in Varna Lake. Beside the Thracian pile settlement excavated in the Urdoviza peninsula's aquatory, a shipwreck has also been studied there. It is a unique in constructive terms sailboat probably from the period XVI–XVII century (c.), and according to Porozhanov (Порожанов 2000, 152), it was used for trading, fishing, or both, given its excellent seaworthiness for navigation in the Black Sea. Exceptionally fruitful for the underwater archaeology was the Black Sea MAP (Maritime Archaeology Project) project, which took place in the period of 2015–2017, with the aim to study the Bulgarian shelf, and deep depth in order to outline the changes of sea level in different historical periods (Милчева 2017). A main participant in the project was the Bulgarian Centre of Underwater Archaeology, which is the only one for the whole Black Sea region. The seabed and the underwater sites have been scanned with multibeam echosounder, which allows the archaeologists to map the sea bottom and thanks to the digital photogrammetry method, to have real 3D images of the underwater sites. Around 80 shipwrecks have been documented during the project implementation, some extremely well preserved and from different epochs (Greek colonization, Roman Empire, Byzantine era, Middle Ages). Specific for all documented shipwrecks is the very high level of conservation due to the oxygen-free environment at the depths of the Black Sea. An almost whole and perfectly preserved shipwreck of a Roman period has been located at 2000 m depth. A unique example is a Genoese or Venetian ship from the XIV century, which is the only known such specimen in the world, and which for now on is only known from images on ceramic pottery. The earliest shipwreck is dating back in V century BC (Greek colonization) at 1700 m depth with ropes rigging still preserved. All shipwrecks have their 3D models produced in the course of the project. This successful project sets Black Sea on the world archaeology map.

The excavated and documented archaeological sites on land along the Bulgarian coastline are also numerous.

Starting from north to south, first in the list is the so-called Big Island in the Durankulak Lake – a place with a thousand years of history. During systematic archaeological studies of the tell on the island prehistoric necropolis, Eneolithic buildings, a settlement from the Late Bronze and

Early Iron Age, Ancient cave temple, Ancient funerals and sacrificial pits, Medieval dwellings, and Ancient Bulgarian necropolis were found and excavated.

An archaeological reserve, also designated as a protected area in 1987, due to the rare and endangered plant and animal species and their habitats, is Yayla terraced area. Several necropolises and rock tombs, an Early Byzantine fortress and a Late Antique winery, cave dwellings, a rock sanctuary, and a rock church were archaeologically studied on the territory of the reserve.

The longest cape along the Bulgarian Black Sea coast and the fortress on it are known today as Kaliakra. The fortification system was being built, developed, and restructured for two millennia (second half of the IV c. BC to XVI c. AC) in three stages with three fortress walls. In this way, the Roman authority in Little Scythia not only adopted the Thracian principle of fortress construction but continued and further developed it (Джингов et al. 1990, 184). The archaeology of the site is represented by Thracian sanctuary, hydraulic system, and monumental public building from the Eneolithic, Roman bath, Ancient, and Medieval necropolis, etc.

In today's town of Balchik (the Ancient Dionisopolis), remains from the Hellenistic, Roman, and Ottoman period of fortification and reconstruction were found. The time have captured remains from the fortification system; from several temples (of God Apollon, Diana and Apollo from Pithya) and a unique Thracian temple "Pontic God's Mother," localized by the found marble fragments of statues and votive tiles; numerous fragments of statues of other gods, too; many tombs; and the earliest Bulgarian bi-ritual necropolis.

The city of Varna has retained its name since the Middle Ages when it was built on the remains of the Ancient Odessos. Toncheva (Тончева 1964, 6) describes Odessos as a large harbor/port slave-owning city-state founded in 570 BC by brave Greek colonists from Milet – an Asia Minor city. The remains of Ancient Odessos include fortress walls and towers, Late Antique streets and buildings, Roman baths, and Early Christian churches. But even before the colonization of this territory, there was life in the Eneolithic era, which continued in the Early Bronze Age, too. The Varna archaeology encompass several chronological periods and a huge variety of objects and archaeological finds. The Chalcolithic here has bequeathed us the oldest gold in the world.

South of Varna, on St. Atanas Cape, is situated a multilayer site with archaeological remains from different historical periods (Йотов and Минчев 2013). A few structures from the Archaic to the Roma epoch have been preserved: Thracian cult center (VI c. BC–I c. AC) and Heracles Sanctuary (I–III c. AC). Most of the sites and remains are dated back in the Late Antiquity, and the main site from the period is the fortress (end IV–beginning VII c. AC) – small harbor/port city with residential structures, wineries, ergasteries, and early Christian sacral center with baptistery.

On an island with 25 hectares area, artificially connected to the land, is located Nessebar – a small Black Sea town, which plays an important role in the religious, cultural, and trade life in the Antiquity and Middles Ages. And today Nessebar impresses with its extremely well-preserved forms of Medieval church architecture and Renaissance housing structures. Parts of its fortification system, remains of buildings, water supply system, furnaces, pits, and an extremely representative necropolis from different historical periods have been excavated on its territory. The archaeological material takes us back to the second millennium BC, when Ancient Nessebar traded with other Black Sea and Mediterranean people via sea routes. The Ancient City of Nessebar is part of the UNESCO World Heritage List of immovable cultural properties since 1983.

During the Antiquity and the Middle ages Anhialo (today's town of Pomorie), which from Greek means "close to the salt" (Кузев and Гюзелев 1981, 356), was located between the Salt Lagoon and the Bay of Burgas, where its fortified settlement existed till XII c. (Лазаров and Гюзелев 2013, 13). Anhialo was famous for not only the salt extraction/production but with a unique Thracian domed tomb, too. In center of the tomb, covered with a brick

annular semi-cylindrical vault, rises a hollow column that extends upwards like a mushroom and merges with the round wall of the hall. This structure makes the Anhialo tomb one of the most brilliant works of ancient architecture, unknown elsewhere (Лазаров 2013, 33).

Remains of buildings from the Classical era, remains of an early Byzantine fortress with a fortification system (4 towers were excavated), and in the fortified interior space – remains of more than ten structures and marble elements, which implies the presence of a temple, were documented on Cape Accra, next to the town of Chernomorets (Христов 2013a). The fortification system continues underwater in the Gulf of Vromos, which is below the sea level today as a result of transregressive processes over time. The excavated structures in the south-east part of the gulf are an anonymous ancient trade settlement – an emporium situated in the directly controlled urban area of Apollonia Pontica.

Apollonia Pontica (today Sozopol) is a complex, multifaceted, rich, and interesting in cultural and historical aspect site. Its existence dated to the Neolithic and Early Bronze Age, evidence of which has been discovered during archeological excavations on land and underwater. The Apollonia's necropolis is impressive in terms of territory and number of burial facilities. The historical part of the town is now an archaeological reserve and it keeps remains from the settlement and from the fortification, which was reconstructed in the Middle Ages. Middle Ages are the period when churches and monasteries were built. On the Sozopol's island St. Ivan a huge monastery (St. Yoan Prodrom) with exquisite architecture, two temples with murals and a scriptorium operated (Попконстантинов et al. 2009, 712). A relic probably with Yoan Batist was discovered on the island. Several production complexes were in operation at the time of habitation on the territory of Apollonia Pontica: production of sgrafito pottery; foundry furnace and smithy; metallurgical workshop with archaeological material, attesting completed technological process of bronze production, etc.

Impressive is the cultural and historical heritage from the village of Sinemorets. Two Thracian tombs and fortified settlement with remains from two chronological periods (Hellenistic and Ottoman) were excavated on and around its territory. Of particular interest to the science are the results of the archeological excavations, during which a burial of a rich Thracian noble woman was studied in one of the mounds. She was probably a priestess with aristocratic social position. A unique coin treasure was discovered within the Hellenistic fortification, which gave a new impetus to the research on coinage during the Thracian ruler Mostis (Йорданов, Агре 2016, 45).

The maritime culture of Thracia Pontica should also be mentioned in the context of Bulgarian maritime cultural heritage as it has been formed within the boundaries of the three seas – Ponta (Black Sea), Propontida (Marble Sea), and Thracian Sea (Aegean Sea). Remains from the Thracian rock sanctuary were located on cape Beglik Tash (Fig. 3, p. 10). All the elements from the cult rock complex are from unrefined natural rocks and roughly carved stone slabs. Thus, the Thracians preserved the natural monumental appearance that they deified as a symbol of eternity (Дражева et al. 2004, 155). The most popular pre-Greek temple in Thracian Pontica and in the whole East Mediterranean world was situated on Samothrace island (today a Greek island in Aegean Sea) (Фол 2009, 68). The Samothrace gods were patron saint of sailors and shipping and this cult extended north of Samothrace (Фол 1998, 11).

There are some other sites from different historical periods excavated along the Bulgarian Black Sea coastline – around Chirakman cape, Bourgas, Sozopol island St. Kirik and Julita, Urdoviza (today Kiten), Ahtopol, etc. and represented by settlement structures, fortresses remains, necropolis, religion temples, etc.

Part of the maritime cultural heritage is also its intangible expression or the traditional maritime culture, because it is a product of the interaction between people and the sea. And this interaction determines the characteristics of the maritime culture of the people living in the coastal region. Part of the traditional maritime culture are the typical for the region fishing

Bulgaria: Maritime Cultural Heritage Management, Fig. 3 Thracian rock sanctuary on cape Beglik Tash

nets and fishing tools; traditions in the shipbuilding and boatbuilding; customs, rituals, and beliefs for good catch; practices related to the worship of the saints of sailors and fishermen; types of edible fish and their conservation; methods for salt extraction/production; fish trading; etc.

Key Issues/Current Debates/Future Directions/Examples

The need for activities toward successful management and socialization of maritime cultural heritage in Bulgaria is indispensable. As shown in the lines above, Bulgaria possesses a large collection of maritime archaeological, historical, and cultural resources, which high cultural potential can arouse public interest to them, if they are effectively preserved and successfully popularized. Oppose to that, at present, the management and socialization of this heritage in Bulgaria are almost not presented. There are still just a few examples of successful managing practices. The possible reason for this is the insufficient activity in this direction. In the field of maritime cultural heritage, our society just begins to understand and measure the globalization effects. The cultural tourism with its cohesion with the trends of the rapidly developing global economy creates an increasing need and demand for intercultural and international contacts, and interdisciplinary education. Bulgaria also has the cultural resource to take an active part in such international initiatives. This will be of great importance for the international promotion of the Bulgarian maritime cultural heritage, for its preservation, and for registering of Bulgaria on the world's cultural heritage map. In this context, the need for sustainable cultural tourism should be emphasized, because the cultural tourism must under no circumstances compromise the physical condition and characteristics of any maritime cultural sites.

The cultural heritage does not play role only on the global scene but it is also a mechanism for building local identity. This is the reason why it is extremely important the local communities to be

involved in the cultural heritage preservation, whether terrestrial or underwater.

Maritime cultural and historical heritage in Bulgaria need public support, because it has not yet firmly established itself in the mind of the population as a resource that must be protected and managed rationally. Adequate, active, and purposeful actions for management and socialization of Bulgarian maritime cultural heritage will be developed; the studies and the popularization of this heritage will soon impose a change in the mindset and the attitude of Bulgarians, and in the cultural tourism sector. With a well-developed national policy on management and socialization of cultural heritage, as well as with the penetration of educated and qualified professionals, and with the support of the society, there can be real opportunities for development of successful management programs. These programs will guarantee not only the Bulgarian maritime cultural and historical heritage physical survival but also its social accessibility, and thus, the sustainable development of the seaside region.

However, there are few examples for successful management practices. Late Antique fortified settlement with port on the St. Atanas Cape, Byala, with winery, medieval basilica, baptistery, etc., which have been restored and reconstructed (Fig. 4, p. 11). The monastery St. Anastasia and other buildings on the island of the same name have been restored and turned into a functioning museum, old-fashioned pharmacy, restaurant, and places for relax. Additionally, there are several museum exhibitions – two devoted to underwater archaeology and the other representing in traditional museum environment (in archeological, historical, and ethnographic museums) the tangible cultural heritage.

But there is still much more to be done regarding the maritime cultural heritage management. The main part of the management approaches in

Bulgaria: Maritime Cultural Heritage Management, Fig. 4 Medieval basilica in the Late Ancient fortress on St. Atanas Cape

the process of socialization of the maritime cultural and historical artifacts is their protection, conservation, assessment of their condition, and of the risk of significant increase in tourists' visits. Apart from the needed regulatory changes, the management approaches toward preservation of the tangible and intangible cultural heritage for the future generations encompass establishment of guidelines for development of underwater reserves with controlled access; criteria for declaring "reserve" status for shipwrecks or archaeological underwater structures; Stone Anchors Corps database, which is supposed to include the physical description of the anchors, petrographic analysis results, 3D images (of all anchors, and of some of the most significant anchorages), mapping of their place of discovery; National Register of Archaeologically Important Maritime Sites; and National Register of Bulgarian Traditional Maritime Culture.

The stone anchors are artifacts of not only local or national but of international importance. Some of them are of foreign origin but were found in Bulgarian waters due to international seafaring and international trade contacts. The sea routes were important dynamic determinants in the maritime cultural landscape, and usually the only way to draw these routes is the presence of stone anchors. The fact that the main types of stone anchors from the Bulgarian Black Sea are like those found in the Mediterranean provides a new perspective to the study of European navigation history. If a Stone Anchors Corps is developed as part of a management strategy, it will turn into a main instrument for deeper study of the European maritime history, types of vessels, maritime routes and trade, international maritime contacts, etc. in the Ancient times. Such interdisciplinary project will build strong relations between IT, science, geology, culturology, education, art, and tourism. This approach will create a net between all maritime countries, in which waters stone anchors (or part of anchors) were found.

Analogical to this database, an Amphorae Corps of objects found in the Black Sea could be developed as part of the management strategy for maritime cultural heritage.

National Register of Archaeologically Important Maritime Sites should include: all types of archaeological objects; all documented shipwrecks; shipwrecks which identity has not been determined yet; underwater ports, harbors, and port facilities; underwater fortresses; submerged settlements, and other structures, etc. The description of each object should cover all the information known about it, the context of its discovery, 3D images, and recommendations for its preservation.

Part of the maritime cultural heritage is the intangible heritage, too. The coastline inhabitants are perceived as guardians of the intangible maritime cultural heritage, as their connection to the coast and the sea is intrinsic of their identity (Borek 2015, 157–158). Intangible cultural heritage is preserved by the society whose members practice and recreate its forms of expression. It is not fixed and unchangeable in time. As it is alive and dynamic, it will always change. Therefore, a National Register of Bulgarian Traditional Maritime Culture should not be considered as an archive but as a living organism that should be updated periodically.

To the list of management approaches should be added the maritime cultural trails – underwater and along the coastline. The underwater trails, and underwater reserves and parks around shipwrecks are a proven in situ method for promoting public access to maritime cultural sites. But adequate management is needed to maintain the maritime cultural heritage and its physical and biological environment. In Bulgarian context, appropriate underwater trails may cover the themes of shipwrecks, ports and anchorages, settlements. The cultural trails on land can be represented by lighthouses; fortresses; tombs and necropolises; churches and monasteries; Thracian mysteries (including Thracian sanctuaries, rock sanctuary, temples, and cult centers excavated and documented along the Bulgarian Black Sea coast).

Although Bulgaria is rich of maritime cultural heritage artifacts and sites, it still does not have a national maritime museum. Its development is crucial for the management of this heritage in Bulgaria. Because of the traditions of this European country in the shipbuilding and

boatbuilding, a Museum of Shipbuilding should be considered as an appropriate option this tradition to be shown to the broader audience. An interactive Museum of Navigation on the Bulgarian Black Sea will represent the history of the lighthouse's construction and maintenance from the mid XIX century to modern times.

Many of the historical and archaeological sites on land have the opportunity to be developed as open-air museums: Anhialo Salt Marshes; Prehistoric necropolises; Apolonia open-air museum (including production complex for sgrafito ceramics, limestone mining quarry, metallurgical workshop, scriptorium for manuscripts and their binding, foundry and forge); Sea fishery and fish market; etc.

The Bulgarian government currently devotes limited resources to management and socialization of maritime cultural heritage, the alternative of the public funding is the public-private partnership, the transborder cooperation between Bulgaria, Romania and/or Turkey, international cooperation with the other Black Sea countries, etc. We, as members of the society, must strive to preserve our common cultural heritage in order to guarantee its survival for future generations.

Burger, Richard

Nicholas E. Brown
Department of Anthropology, Yale University, New Haven, CT, USA

Basic Biographical Information

Richard Lewis Burger (Fig. 1) is an anthropological archaeologist from the United States known for his work on the emergence of civilization in the Central Andes. Born in Manhattan, New York on September 4, 1950, he was the oldest child of Norman Burger, a lawyer and CPA, and Marion Levy, a bacteriologist and special education teacher. Both of his parents were archaeology enthusiasts, and his father served as the first president of the Long Island Chapter of the Archaeological Institute of America. Burger was educated in the public school system of Great Neck, New York. He received a bachelor's degree in archaeology in 1972 from Yale College, studying under Thomas Patterson and Michael Coe, and a doctorate in anthropology from the University of California, Berkeley, in 1978, studying under John Howland Rowe and Dorothy Menzel. Burger is married to Peruvian archaeologist Lucy

Burger, Richard, Fig. 1 Richard Lewis Burger

Salazar, with whom he has collaborated on many research projects.

Burger joined the faculty at Yale University in 1981 and is the Charles J. MacCurdy Professor in the Anthropology Department, chair of the Council on Archaeological Studies, and Curator in the Division of Anthropology at the Peabody Museum of Natural History. While at Yale, he has served as chair of the Anthropology Department (1990–1994) and as director of the Peabody Museum of Natural History (1995–2002). In Peru, he has taught at the San Marcos University (UNMSM) and the Catholic University (PUCP) in Lima and is an honorary member of the faculties of the University of Cusco (UNSAAC) and the University of Iquitos (UPI). He serves as co-curator in the Museo Machu Picchu, Casa Concha in Cusco, Peru, and since 2006 has been president of the Institute of Andean Research in New York.

Burger has directed numerous field projects in Peru, with a particular focus on the northern highlands and central coast. For his doctoral research, he directed the Chavín/San Marcos Archaeological Project (1975–1976) in the Callejón de Conchucos, Áncash, that included excavations at Chavín de Huántar, Pojoc, and Waman Wain. For his postdoctoral research, he directed the Huaricoto Project (1978–1980) in the Callejón de Huaylas, Áncash, as well as the Lurín Valley Project that included excavations at Cardal (1984–1987, 2007–2008, 2017–2019), Mina Perdida (1990–1991, 1993–1994), and Manchay Bajo (1998–1999) in the Lurín Valley, Lima. He has led survey projects in the south-central highlands of Huancavelica and Ayacucho (1999–2000) and Apurimac (2003–2006) to identify obsidian sources.

Upon the completion of his doctorate, Burger was awarded the Organization of American States Postgraduate Fellowship, and he has served as chair of the Senior Fellows of Pre-Columbian Studies at Dumbarton Oaks, Washington D.C. He received the Seton Elm-Ivy Award by Yale University and the City of New Haven for his activities as director of the Peabody Museum, the Wilbur Cross Award Connecticut Humanities Scholar of the Year by the Connecticut Humanities Council for his role as co-curator of the traveling exhibit on Machu Picchu, and the Phillip Johnson Book Award by the Society of Architectural Historians for the exhibit catalog of the Machu Picchu exhibit (Burger and Salazar 2004).

Major Accomplishments

Burger's theoretical focus in archaeology is the emergence of civilization. He favors a definition of civilization as "a society with a high level of cultural achievement in arts and sciences as made visible in the form of material objects" (Burger 1992: 9), a qualitative and subjective framing that is more in line with the common usage of the term than the trait list approach of V. Gordon Childe. While acknowledging that all civilizations are complex societies, given that advanced cultural accomplishment implies the existence of a body of esoteric knowledge, specialized artisans, surplus labor/food, and the social mechanisms for its appropriation, Burger argues that the sociopolitical basis of each civilization must be left open for investigation rather than assumed to be shared among all cases. This approach focuses attention on the emergence of complexity and its cultural expression without anticipating (and biasing) the results by incorporating them into definitions of the terms civilization or complex society.

Burger has dedicated his career to understanding the sociocultural processes behind the rise of early

civilizations in the Central Andes. Part of this effort has been synthesized in his book, *Chavín and the Origins of Andean Civilization* (1992). He suggests that the developmental trajectory followed in Peru may represent a pathway dissimilar from those documented elsewhere and that the organization of early Andean civilization may have been fundamentally different from those civilizations in the Old World and Mesoamerica. Burger argues that only once the range of variation in the emergence of the world's earliest civilizations is known can anthropologists begin to formulate coherent explanations for their appearance. By studying the emergence of indigenous civilizations in the Central Andes, archaeologists can begin to question the universality of Western narratives regarding early complexity – such as the importance of states and elites – and discard biases against non-Western institutions and knowledges.

Much of Burger's research has focused on how religious institutions, rather than stratified states, constituted the primary source of power among early Andean civilizations. In taking humanity's interest in the divine seriously, rather than viewing it as beyond the purview of scientific archaeology, Burger's research has opened up new interpretative possibilities for how and why complex social organizations developed in the case of the Central Andes.

The Late Preceramic Period (3500–1800 B.C.) marks the first time that Andean peoples came together to create monuments as the physical expressions of their social organizations. Burger and Salazar's work at the site of Huaricoto has discerned a pattern of early monumentality in the north-central highlands in which different segments of a small-scale society came together at a single site to build small chambers with central hearths for burnt offerings (Burger and Salazar-Burger 1980). They describe this architectural pattern the "Kotosh Religious Tradition," drawing attention to the fact that these chambers were used exclusively for ritual offerings and kept clean of any other activities. These ceremonial centers of clustered ritual chambers constitute the earliest monuments in the Peruvian highlands and demonstrate the importance of religion as an integrative force in very early complex societies in the Central Andes.

The Initial Period (1800–800 B.C.) saw the continued development of monumental architecture in the Central Andes with the appearance of discrete cultural traditions along the coast, highlands, and tropical forest. Burger and Salazar have conducted long-term research on the tradition of U-shaped temples of the Manchay culture on the central coast of Peru. Focusing on the Lurín Valley just south of the Lima metropolitan area, they have excavated three large U-shaped temples of Cardal, Mina Perdida, and Manchay Bajo. These civic-ceremonial centers served religious and political functions as sites where people living in nearby villages would carry out periodic ritual activities like processions and offerings (Burger and Salazar 2008). Based on many seasons of excavations, Burger has shown that there is little evidence for social stratification, long-distance trade, or large resident populations at these centers. In analyzing the architectural sequences of U-shaped temples, Burger has shown that they were built as many small construction episodes over long periods of time and could have been constructed by relatively small groups of people. From these data, Burger argues that the basis of Manchay ceremonial centers was not a stratified state apparatus but rather an egalitarian religious institution that linked a multitude of small-scale independent sociopolitical units.

By the Early Horizon (800–200 B.C.), the Chavín religion appeared as the first sociocultural phenomenon with the artistic and scientific achievement of civilization that affected the Central Andes as a whole. This innovative religious ideology known for its elaborate iconography spread from civic-ceremonial centers like Chavín de Huántar across a large swath of Peru, creating a context of interacting societies that saw watershed advances in metallurgy, weaving, hydraulic engineering, trade infrastructure, botany, husbandry, mining, and lithic technology (Burger 1992). Burger's chronological and socioeconomic studies of Chavín de Huántar (e.g., Burger 2019) have illustrated that in the context of the Chavín religion, Andean civic-ceremonial centers developed into sites with proto-urban resident communities, elite differentiation, and asymmetrical trade relations. Burger's research has shown that these traits,

hallmarks of civilization elsewhere in the world, only appear in the Central Andean case after many millennia of sociocultural processes related to the formation of religious institutions.

Burger's research on the development of civilization at interregional scales has led him to develop scientific techniques for studying the long-distance movement of artifacts made of obsidian and cinnabar. Alongside Frank Asaro, he carried out a pioneering geochemical study of obsidian artifacts that successfully identified distinct obsidian sources used in the ancient Central Andes (Burger and Asaro 1977). With these chemical groups identified, Burger and colleagues carried out surveys in the south-central highlands of Peru to find the physical locations of obsidian sources (e.g., Burger and Glascock 2000). Similarly, with Colin Cooke and Holger Hintelmann, Burger has pioneered the sourcing of cinnabar and demonstrated the long-term importance of Huancavelica, the area responsible for producing most of the cinnabar traded over long distances throughout prehistory (Burger et al. 2016). With the links between artifact and source location laid bare, greater understandings of the social and historical processes involved in exchange can be created. Burger's combination of scientific and humanistic approaches has also led him to engage in iconographic analysis as well as collaborate in faunal and carbon isotope studies. Burger and Salazar have also made important contributions to Inca studies through their exhibitions and analyses of Hiram Bingham's Machu Picchu collections, first at the Yale Peabody Museum of Natural History (Burger and Salazar 2004) and then at the Museo Machu Picchu, Casa Concha in Cusco.

An overarching emphasis of Burger's research agenda has been the creation of detailed site chronologies using ceramic, radiocarbon, and architectural data. He maintains that a firm chronological framework is indispensable for analyzing diachronic developments and incorporating them into larger frameworks of prehistory. Additionally, his research consistently highlights the importance long-distance interaction in the past and the creation of interregional theoretical frameworks for the purpose of coherently integrating regional data sets. Burger's goal of crafting a better understanding of time and space in the Central Andes comes from his enduring appreciation of culture-history as foundational for achieving any of the interpretative goals of other theoretical movements, processual, post-processual, and beyond.

Burial Archaeology and the Soviet Era

Jussi-Pekka Taavitsainen
Department of Archaeology, University of Turku, Turku, Finland

> Also the dead remain silent – until it is time for them to speak.
> Stanislaw Jerzy Lec

Introduction

There is something paradoxical in the fact that in 1943, the representatives of one totalitarian dictatorship, the Germans, began the excavation of the graves of the victims of another totalitarian dictatorship, i.e., the Soviet Union. The location was the site of the mass murder of Polish officers, NCOs, and officials at Katyn in Russia (e.g., Drazkowska 2010; Johansson 2010). The Stalinist terror (e.g., Conquest 1992) applied not only to the citizens of the Soviet Union but also to segments of the population regarded as politically dangerous in the areas conquered and occupied by the Soviets. It must also be mentioned that the archaeological profession suffered heavily from the terror (e.g., Klein 1997; Formozov 2006; Platonova 2010: 184–188).

After the collapse of the Soviet Union, the search for the remains of the victims of the terror and their exhumation has become a new area of work for archaeologists. Numerous mass graves have been discovered, but there have also been systematic searches for them. The reasons for this have been above all human, humanitarian, and political. The work of locating these grave sites outside the Russian Federation has been carried out actively in the Baltic republics, Poland, and the Ukraine (Tamm et al. 2008). In human terms, the need for archaeological and physical-anthropological exhumation is obvious and needs no explanation. The nations, ethnic groups, families, and individuals that experienced the terror have finally been given a chance to know the fate of their lost members and loved ones and their possible places of burial and to complete the process of individual and collective grieving (on the commemoration of the terror in present-day Russia, see Etkind 2009, and on commemoration and role of Katyn in European memory, see Etkind et al. 2012). According to Zoe Crossland (2011: 286 and cited literature), this involves "the increasingly pressing question of the memory and commemoration of recent conflict."

Apart from the human aspect, the reasons for investigating the material remains of the Soviet terror can be summarized as three main considerations (see, e.g., Zemitis 2005): (1) the legal aspect with research for the purposes of establishing historical truth and possible crimes against humanity (e.g., Kalbarczyk 2008), (2) the preservation and cherishing of the memory of the dead, and (3) to generate interest in history. The goals of national unity have also been in the background, and the present administration seeking reforms has reinforced its own legitimacy by revealing the victims of the old system of government (Paperno 2001: 89–90).

Since these investigations, however, are due more to human, humanitarian, and political reasons than the actual needs of research, their nature cannot always be merged with archaeological or

forensic procedures in completely unproblematic ways (Crossland 2011). The Estonian, Latvian, and Lithuanian research teams, however, involve a prominent archaeological, physical-anthropological, and medical contribution. They have also made use of expertise from beyond their own national borders (e.g., Lõugas 1991: 83). Lithuanian experts, in particular, have been employed in the other Baltic countries. The origins of Lithuanian forensic anthropology date from the 1960s, one of its roots being the exhumation of mass graves of the Holocaust (Garmus and Jankauskas 1999). Thus, the Soviet system provided the necessary training for later exhumation work.

Key Issues/Current Debates/Future Directions/Examples

Investigations have been organized in the Baltic countries by the institutes of archaeology of the national academies of science, the departments of archaeology, medicine and anthropology of the universities, and antiquarian societies (Tamm et al. 2008). This work has also involved large numbers of volunteers, various state and municipal bodies, and organizations including the successors of the state security organizations.

These investigations have produced much genetic material. In 2013 in Poland, to intensify the use of this material, together with archaeological and historical evidence, the Pomeranian Medical University in Szczecin founded the Polish Genetic Database of Victims of Totalitarianisms (PBGOT, www,pbgot.pl) to identify the remains of unidentified victims of both Communist and Nazi totalitarian regimes (Ossowski et al. 2016).

While the investigations have primarily concerned mass graves, execution sites of officers and other ranks of national armies and places where resistance fighters of the long period of occupation were killed have also been excavated. (Pillak 2016a: 184–185). A separate area of work consists of locating the graves of heads of the state and other dignitaries and the identification of their remains (Jankauskas et al. 2008). The grave and remains of Konstantin Päts, the last president of the first Estonian Republic, for example, were located, and the remains were reinterred in a solemn state ceremony in Tallinn (Lõugas 1991; Verdery 1999; Puustak 2008; Pillak 2016b), while the body of Karlis Ulmanis, the last pre-Soviet president of Latvia, has not been found (Zemitis 2005: 2). The remains of Prime Minister Imre Nagy of Hungary have also been exhumed (Tallai and Keve Kund 2008).

There was, in fact, interest in the Soviet Union in the remains of dignitaries and especially of Tsar Nicholas II and his family. There was a secret search for them already in the late 1970s, and investigations were officially resumed in 1991, leading to the scientific identification of the remains, their reburial, and canonization (Rousselet 2011). In Russia, however, the main focus has been on investigating the burial sites of victims of mass murders. The main organization involved in this work is Memorial (http://www.memo.ru), which also operates in Ukraine, Kazakhstan, Latvia, Georgia, and Italy, in addition to Russia. One of Memorial's main objectives has been "the awakening and preservation of societal memory of the severe political persecution in the recent past of the Soviet Union." In fact, the perpetuation of the memory of the victims was the very idea around which Memorial was formed. These activities have involved the preparation of "Books of Memory," special publications listing victims of Soviet repression (e.g., Gil'di and Braudze 2010). Memorial's activities have been actively followed and hindered by state authorities. It has have declared to be a "foreign agent," an organization accepting foreign funding and being engaged in political activity. Even its "liquidation" has been suggested (https://en.wikipedia.org/wiki/Memorial_(society)).

The main part of the work of Memorial has been the search for the burial sites of victims of the terror and related exhumation. The Soviet terror particularly concerned ethnic minorities, and some examples and results from their territories can be presented. Large numbers of mass graves

have been found in Russian Karelia, including Sandarmokh in the District of Medvezh'egorsk (Karhumäki), the largest known burial site of victims of the Stalin terror of 1937–1938 in Northwestern Russia, which was discovered in 1997 (Etkind 2009: 182–184). The 9,000 executed victims at Sandarmokh represent approximately 60 different nationalities (on burial sites in Karelia, see, e.g., Trubin 1989; Korablev n.d.).

In the Republic of Mari El in Central Russia, research was launched during the period of *perestroika*, and as early as by 1991, at least 12,000 bodies had been found in 200 identified mass graves (Patrushev 1991) within a 13-km radius of Joskar-Ola, the capital of the republic. The purges were particularly aimed at liquidating the intelligentsia of the Mari people. By way of comparison, it should be noted that under Stalin the republic had a population of approximately 600,000.

The work of the association of children of the victims of the repression of the Mari is an example of how searches were carried out for the graves. Firstly, people with knowledge of the executions were sought and interviewed. Eye-witness accounts were supported by aerial photographs of forested areas from 1955 with the notable detail of depressions on the surface of the ground where no trees grew. The investigations involved the local authorities and students of history at the Mari University under the direction of an archaeologist. The excavations revealed details of execution methods, and artifacts ranging from the headwear of members of the national intelligentsia to officers' sword belts pointed to ethnic and professional groups. The artifacts indicate the wide social spectrum of the victims. The process also included the erection of monuments at the burial sites (Patrushev 1991).

The research conducted in Mari El is a good example of the investigation of graves. The results include the surveying of burial sites based on archive materials, interviews, and aerial photographs, establishing the numbers of victims and their ethnic and social backgrounds, the reconstruction of methods of execution, and remembrance. For the time being, compilations of this area of archaeological work have not appeared in the former area of the Soviet Union. Katyn and other execution sites of Poles were not the only mass graves excavated and studied by the Nazis. Paradoxically, the results concerning the mass graves at Vinnytsia, issued in 1944 by the publishing house of the National Socialist Party, are still the most thorough forensic studies of mass graves from the area of the former Soviet Union (Paperno 2001 and literature therein).

In some cases, excavations have left unverified the wildest assumptions concerning grave sites. There is also, e.g., a rumor in Minsk that the local porcelain factory tried to improve its wares by adding powdered bone of human skeletons collected for this purpose. No one has yet been able to prove this claim, but people familiar with the period believe that it may well be true (Lõugas 1991: 80).

As Lõugas (1991: 84) writes: "Every East European archaeologist is familiar with the Early Iron Age 'kosti' of Glayadenevo Baskiria, 25 km from the city of Ufa. It is a mountain of bones, containing the remains of thousands of animals. This site is a well-known point of departure and comparison for the study of similar sites and antiquities of smaller scale. Perhaps a chronological starting point for future archaeologists will be the 'East European and Siberian layer of bones' from the second quarter of the twentieth century."

Military graves in the former Soviet Union must also be mentioned in connection with Soviet-era burials. Interest has now arisen in Russia in keeping and maintaining them. The Red Army usually left its dead unburied in the field. Now the remains have begun to be collected into military cemeteries, the care of which has begun.

An additional theme here consists of the burial sites and remains of lost soldiers of former enemy nationals in the present area of the Russian Federation. An example is the situation involving Finland and the Soviet Union/Russia. Finns have shown interest in the Finnish war dead of the areas ceded to the Soviet Union and the repatriation of

their remains. This work was launched by the Finnish Ministry of Education, and it has led to a Finnish-Russian agreement on keeping the memory of both Finnish soldiers who died in Russia and Russian (Soviet) soldiers fallen in Finland and an official statute on its implementation. These activities are of a bilateral nature. Finns assist Russians in their search for remains of soldiers in Finland, provide information on finds of this nature, and participate in keeping and maintaining the grave sites.

There are also results from Finland. The Association for Cherishing the Memory of the Dead of the War (http://www.sotavainajat.net/perussivut/sivut/english.htm; see also Blinnikka 2004) continues the work previously carried out by the Ministry of Education. This work and its results are cited below as described by the Association.

In practice, the work involves searching for and bringing back remains of Finnish soldiers from the battlefields of the wars of 1939–1945 that are currently located in Russia. During the wars between 1939 and 1945, approximately 13,000 Finnish soldiers were either lost on the battlefields or reported missing. The identification of the dead and their burial in their home areas is the main goal of the work. The remains of more than 1,100 Finnish soldiers have been found so far. Of these, the identities of almost 400 soldiers have been established. The majority of the c. 90,000 killed were evacuated and buried in the home graveyards (on repatriation and identification, see Palo et al. 2007).

Another field of activity is the restoration and maintenance of seven field graveyards in the ceded territory. These were established during the war and are today a final resting place for nearly 900 Finnish soldiers. Later, monuments have been raised at each of these graveyards.

During the wars of 1939–1945, around 4,000 Finnish soldiers were captured as prisoners of war. Of them, a little more than 2,100 were able to return to Finland after the war. It has been confirmed that 760 soldiers perished during their captivity. The fate of the others is still unknown. Five monuments have been raised in the locations of the former prisoner of war camps for those who perished there.

Burial Excavation, Anglo-Saxon

Martin Carver
Department of Archaeology, University of York, Kings Manor, York, UK

B

Brief Definition of the Topic

Human burials constitute a major source of evidence for human history. Burials excavated by archaeologists may report on both the individual commemorated and on society more broadly. Human remains may be encountered as burnt bone in containers or in pits (*cremations*), or as skeletons in graves (*inhumations*), or as mixed collections of bones, created by communal deposition (as in European Neolithic long barrows), or by reburial (*charnel*). The state of the remains (and their potential for further research) is dependent on the local terrain and consequent degree of decay (see "► Site and Artifact Preservation:

Burial Excavation, Anglo-Saxon, Fig. 1 A cremation urn

Burial Excavation, Anglo-Saxon, Fig. 2 An inhumation with typically poor bone preservation. The stones are part of the burial rite

Burial Excavation, Anglo-Saxon, Fig. 3 Plan of a furnished inhumation. (From Sutton Hoo, Mound 17)

Natural and Cultural Formation Processes"; that associated with human remains is termed *taphonomy*). In general, acid soils (e.g., sands and gravels) attack bones, while more alkaline soils (chalk) tend to preserve them better. Anaerobic conditions (excluding air) can preserve the soft tissues. Thus *bog burials* (seen in the Scandinavian Iron Age) have preserved skin and inner organs and even the last meal of the deceased, but the acid solution of the bog has nevertheless dissolved the bone (Glob 1969).

The purpose of excavating cemeteries is to gain an insight into the population and thinking of an ancient community and generally involves two lines of inquiry: the study of the burial rites and the study of the skeletal material. The *burial rites* include the form of the grave, its orientation, and the disposition and character of the objects placed in the grave – the *grave goods*. In burial rites, variat ions in space imply different ranks or families; variations through time may relate to changes in religious or political thinking. *Skeletal material* reveals evidence for basic demography through a study of anatomy: This gives age at death, sex, major diseases, and injuries. The carbon contained in the collagen in the bone (including cremated bone) can be extracted and *radiocarbon*-dated, using the proportions of carbon isotopes. Carbon and nitrogen isotopes present in the bone are also used to assess the emphasis of diet (it will show whether the diet of an individual had a strong or weak marine intake, i.e., fish). Oxygen and strontium isotopes trapped in teeth indicate the character of the groundwater where a person grew up. *Ancient DNA* (aDNA) can now be recognized in skeletal material.

The excavation of Anglo-Saxon burials (fifth to seventh century), used here as an example, has generated a notable range of techniques (Williams 2006; Carver 2009: 131–8). The pits containing cremations are exposed on the surface by troweling, and the pot exposed and removed, intact wherever possible, for excavation indoors (Fig. 1). The contents of the pot are removed in very small spits to document the association of the fragments of burnt bone with each other and with the fragments of grave goods. The objective is to discover which humans, animals, and grave goods had originally been on the funeral pyre.

Inhumations accompanied by grave goods are commonly encountered in Anglo-Saxon cemeteries (Fig. 2). The graves are revealed on the surface by troweling, and the grave fill is then removed in 5- or 10-cm spits against the long axis: This will provide a profile through the grave. The skeleton and all the grave goods (e.g., sword, shield, brooch) are photographed and plotted individually on a grave plan (Fig. 3).

An example of a research project at an Anglo-Saxon cemetery is given by Sutton Hoo. A ship burial discovered by chance at the site in 1939 drew attention to its potential. The site was subjected to a 2-year evaluation in the 1980s, with a view to determining what had survived the effects of taphonomy, plowing, and treasure hunting, and a project design was then published. In addition to regional surveys, this design proposed the excavation of 1 ha of the

Burial Excavation, Anglo-Saxon, Fig. 4 The burial under Mound 17 being excavated from a cradle

4 ha site, encompassing five of the 18 known burial mounds (and the spaces in between).

Burial Excavation, Anglo-Saxon, Fig. 5 A 'sandman' burial' where the form of the body is preserved (but less so the bone).

Several of the mounds contained cremations, two had contained ships, and one contained a young man buried in a coffin (Fig. 4). His horse was buried in a separate pit adjacent. In the later Saxon period (eight to eleventh century), this high-ranking pagan cemetery became a place of execution.

The ground conditions at Sutton Hoo were hostile, and although fragments of bone were sometimes present, human bodies had decayed markedly in the acid sand, creating "sand fossils" rather than skeletons. The majority of burials, still marked by mounds, had been severely pillaged, scattering bone and objects. The medieval use of the mounds as rabbit warrens had further dispersed the burials.

Nevertheless, the horse and rider burial was undisturbed and could be excavated in precise detail. The execution burials (sand fossils) proved susceptible to excavation in three dimensions, and their shapes were sufficient to show examples that had been killed by hanging or beheading (Fig. 5). The chamber in a pillaged mound, Mound 2, was surveyed by intensive chemical mapping, which showed the location of the now vanished body, a copper alloy cauldron, and other grave goods (Fig. 6). In spite of the evident battering the

Burial Excavation, Anglo-Saxon, Fig. 6 Chemical mapping of the floor of a robbed chamber

cemetery has suffered through the ages, there was sufficient bone to radiocarbon-date the whole sequence, from 580 to 1050, and align it with the typological dates of the rich grave goods from the famous ship burial.

Burial Mound Dissection in Sweden

Per H. Ramqvist
Department of Historical, Philosophical and Religious Studies, Umeå University, Umeå, Sweden

Introduction

In 1949, it was decided to excavate the first of the four Migration Period large mounds in Högom at a cemetery a few kilometers west of Sundsvall in the county of Medelpad, North Sweden. Concentrations of large mounds (>20 m in diameter) in Scandinavia are known at Old Uppsala in Uppland, Bertnem in Trøndelag, and Borre and Snartemo. Often arranged in rows, these are high status burials representing generations of regional leadership. The four mounds in Högom ("mounds") Medelpad north Sweden clearly belonged to this exclusive group. When investigations began in 1949, the site had been largely forgotten and was encumbered by houses, barns and cellars, driveways, and threshing places. The National Heritage Board decided to purchase the area, remove the buildings, and restore a cultural landscape around the cemetery. But before restoration, it was decided to investigate the most damaged of the burial mounds (No. 2). The project was one of exceptional innovations.

Key Issues/Current Debates/Future Directions/Examples

The mound was 40-m across and at least 4-m high, and in accordance with the excavation methods of the late 1940s, it was initially investigated with a trench. This was placed on the NE side of the mound on the site of a demolished building. Beneath the topsoil, the excavators encountered a stone cairn, which was then exposed in its entirety (Fig. 1). It proved to be 20-m across, and seen from a tower was clearly no random heap, but the stones had been deliberately sorted by size. To record this information, the whole cairn was carefully planned, stone by stone.

Burial Mound Dissection in Sweden, Fig. 1 Dagmar Selling, excavator (with Sverker Janson) of Högom Mound 2, working on the central cairn (Ramqvist 1992, Fig. 17a)

Burial Mound Dissection in Sweden, Fig. 2 Metal buttons on the leggings of the buried person showing in the compressed roof of the chamber (Ramqvist 1992, Fig. 24)

Burial Mound Dissection in Sweden, Fig. 3 Metal plates being driven beneath the chamber with jacks (Ramqvist 1992, Fig. 25)

Burial Mound Dissection in Sweden, Fig. 4 The encased burial chamber is unloaded outside the laboratory in Stockholm

While the stones were being removed, it became apparent that there was a central burial chamber measuring 5 × 2 m in plan that had been constructed in timber. It had been compressed by the weight of the mound into a compact layer 10-cm thick containing all the wood, the body, and the objects, some of which showed through the matt surface of the compressed wooden roof (Fig. 2). Attempts to excavate the chamber in situ were frustrated by the hardness of the wooden layer; more forceful digging threatened to destroy the objects.

Inspired by the successful lifting of a whale jawbone during the excavation of a Stone Age settlement in Bohuslän (western Sweden) in 1935, it was decided to try and lift the whole chamber in order to excavate it in the laboratory. This much more challenging project was achieved by engineers from the construction firm, Hallström & Nisses of Sundsvall. To provide access, a wide and deep trench was dug around the chamber, making an archaeological record of the layers disturbed. The chamber proved to be resting on silty deposits without a wooden floor.

Burial Mound Dissection in Sweden, Fig. 5 The set of X-ray plates from the eastern part of the chamber showing the bridle and cauldron in position in the laboratory (Ramqvist 1992, Fig 28b)

The engineers then built a wooden box around the chamber and drove steel pipes beneath it, with horizontal steel plates jacked into position above them to create a base for the chamber deposit (Fig. 3). The wooden box was infilled with plaster to prevent movement of the deposit and the whole encased in a steel frame. It was then lifted and transported to the National Historical Museum in Stockholm.

When unloading the box in Stockholm (Fig. 4), it was turned completely upside-down, so that the continuing investigation could take place "from below," with the impenetrable roof now as the base. Before excavation in the laboratory, the entire deposit was X-rayed, producing a set of plates at 1:1 which proved to be an invaluable guide to the indoor excavators (Fig. 5). The burial was excavated in minute detail. Dating to c. 500 CE, it is known as one of the richest and best excavated in the Baltic area.

In 1984, the site was surveyed in detail and the previously unexcavated perimeter around the cairn was examined, revealing large postholes of a building erected before the mound, probably a three-aisled long house. The whole site was eventually published by Ramqvist (1992).

Burial Practices and Tombs in the Roman World

Tracy Prowse
Department of Anthropology, McMaster University, Hamilton, ON, Canada

Introduction

The choices people make about the treatment of the dead can be used to understand a society's attitudes toward death and beliefs about the afterlife. Information concerning burial practices and commemoration in the Roman world come from both ancient texts and archaeological evidence. Ancient literary sources can provide rich contextual evidence for Roman beliefs and practices surrounding death and burial, yet it is important

to remember that many of these ancient sources were written by elite male members of society and likely reflect a limited segment of Roman society. The archaeological record also provides invaluable information on burial practices, but only a small percentage of burials have survived intact from the Roman period and are overrepresented by monumental tombs that belonged to a small elite segment of Roman society. Through the integration of different lines of evidence, general patterns can be discerned, but it is important to emphasize that there was not one universal "Roman" way of burying the dead throughout the Roman world and that these practices varied both geographically and temporally.

Definition

The term "burial" refers to the act of placing the deceased in the ground and can also indicate the location where the deceased is interred, which is often used interchangeably with "grave." "Burial practices" refer to the activities surrounding the preparation of the deceased for burial and deposition of the remains in the ground or in some type of burial structure. A "tomb" can be used to refer to the general location where the deceased is buried, but is more commonly used to describe a freestanding architectural structure that is used to house the dead.

Key Issues

Death Pollution

A number of factors influenced the treatment and burial of the dead in ancient Rome. The widespread belief in death pollution, both spiritual and physical, meant that rituals were required to separate the deceased from the living and to cleanse the survivors of any contamination associated with death (Toynbee 1971; Lindsay 2000). Attitudes toward the dead were also influenced by the belief that some part of the individual continued to exist after death and could influence the living, so appropriate burial practices were required to guarantee a smooth transition into the afterlife. A "proper" burial guaranteed that the deceased made this transition successfully, ensured that deceased spirits were not restless, and helped to reintegrate survivors back into society (Hope 2000).

The period of mourning, known as the *feriae denicales*, began with the death of the individual and ended after the ninth day. Pine or cypress branches were placed outside the front door of the house to advise other members of the community that a death had occurred (Lindsay 2000). Once the body was washed and prepared for burial, either by family members or by hired professionals for more affluent members of society, the body was then laid out for a period of time in the home. For wealthier members of society, the display of the deceased and the funeral procession may have been an elaborate affair involving professional mourners and actors hired to wear the wax masks (*imagines*) of the deceased's ancestors and public eulogies in honor of the deceased in the forum (Flower 1996; Lindsay 2000). For a description of an elite Roman funeral procession, see Polybius (*Histories* 6.53–54). For the majority of people in the Roman world, however, the funeral procession from the home of the deceased to the grave or tomb was likely a modest affair carried out by the family.

The association of death with pollution and contagion also had an impact on the location of burials and tombs. Roman law dictated that burial had to occur outside the sacred boundary of the city (the *pomerium*), with the exception of a small number of elite members of Roman society who were buried within the walls of the city (Patterson 2000; Retief and Cilliers 2006). The tombs of aristocrats and their household members often lined the main roads leading into the city, such as those found along the Via Appia outside Rome and the Street of the Tombs outside Pompeii. Less wealthy members of society were buried in a variety of structures in cemeteries outside the city (see "Burials and Tombs," below), but these cemeteries were often not clearly defined (Hope 2000).

After the funeral ceremony, the participants consumed a meal, the *silicernium*, at the site of

interment or cremation, and food and drink were also offered to the deceased. Food was an essential part of the transition of the deceased from the world of the living to the afterlife, and the ritual of feasting with the dead continued through annual festivals to commemorate the dead. After returning from the funeral, family members and other mourners had to be cleansed of the pollution associated with death with water and fire (the *suffitio*), and the house of the deceased had to be purified to once again reintegrate the survivors back into society. At the end of the 9 days, another meal (the *cena novendialis*) was held to mark the end of the mourning period and the reintegration of the mourners back into society. Some ancient texts also refer to the practice of sacrificing a sow to the goddess Ceres at the grave site so that the burial was legally considered a grave (Lindsay 1998; Erasmo 2008).

Inhumation

Inhumation involved placing the body either directly into the ground or inside a burial container (e.g., coffin or sarcophagus) for burial. If communal tombs were used, the individual might be placed in a freestanding sarcophagus, interred in a space along the walls (e.g., *loculi* in Roman catacombs), or buried in pits in the floor of the tomb. In order to have a proper burial, it was important for soil to be scattered over the deceased; otherwise, the spirit was trapped between the worlds of the living and the dead and would remain restless (Hope 2000; Graham 2006). Disturbing a burial or damaging a tomb was a criminal offense.

The burial or tomb was viewed as the house of the deceased, consistent with the belief in the afterlife and that the spirits of the dead still required sustenance through regular offerings of food and wine, and a permanent place to reside (Patterson 2000; Wallace-Hadrill 2008). The deceased was typically buried with personal items or grave goods that would be of use in the afterlife, such as pottery vessels and oil lamps, although the quantity and quality of the objects would vary according to the gender, age, and status of the individual. The presence, absence, quality, or quantity of grave goods must be interpreted with caution, as changing patterns in burial practices may also be related to shifting attitudes of those responsible for burial (e.g., asceticism). Literary sources from the fifth century BCE to the second century CE also describe the common practice of placing a coin in the mouth of the deceased to pay the ferryman, Charon, for transport across the river Styx to the underworld. The archaeological evidence, however, does not support the ubiquitous use of coins in burials or the consistent placement of coins in the mouth of the deceased when present (Hope 2009). Coins are not found in all Roman burials, and when present, they are found in association with other areas of the body. Thus, the prescribed ideals for Roman burial ritual could be adapted or ignored depending on local customs, cost, and individual choice.

Cremation

Cremation of the dead involved transporting the deceased to the cemetery and burning the body in the location of the burial (*bustum*) or cremating the body in an area of the cemetery reserved for this process (*ustrinum*). In *bustum* burials, the individual was placed on a wooden pyre above the grave, and as the cremation progressed, the burnt remains and ashes would fall into the burial along with any grave goods that were placed with the body. The presence of *bustum* burials can be recognized archaeologically by the presence of cremated remains interspersed with ash and traces of carbonized wood (Fig. 1). These funerary pyres did not usually produce enough heat to fully incinerate the bones of the deceased, so carbonized bone fragments are often present. Once the pyre cooled, the remains were sprinkled with wine and the grave would be filled in by soil and/or covered by a more permanent tomb structure.

After the deceased was cremated in an *ustrinum*, the remains were sprinkled with wine and soil and then placed in a container that would eventually be interred in a columbarium or family tomb (see "Burials and Tombs," below). Remains of *ustrina* from the Roman period have been found associated with the mausoleum of Augustus in the Campus Martius and along the Via Appia outside Rome. The preparation and tending of the

Burial Practices and Tombs in the Roman World, Fig. 1 In situ cremation burial (*bustum*) showing areas of carbonized wood (left) and ash (lower right). Cremated bone is distributed throughout the burial and grave goods are in the foreground

funerary pyre likely required specialized knowledge in order to ensure that the remains would be properly cremated and required the skills of a professional pyre burner (*ustor*) (Noy 2000; Graham 2006). An incomplete or partial cremation was considered an insult to the deceased and was potentially dangerous to the living because the deceased had not been properly laid to rest (Noy 2000). The ancient authors Cicero and Varro describe the practice of removing a fragment of the body (*os resectum*) prior to cremation for later reburial, which is attributed to the requirement of symbolically burying the deceased to ensure a proper burial (Retief and Cilliers 2006). This ritual is often described in the literature on Roman burial practices, although obtaining archaeological evidence for this practice is unlikely due to the fragmentary nature of cremated remains and the uncertainty concerning where the body part, usually described as a finger bone, would later be deposited (Hope 2009). It has also been suggested that the body fragment would be placed in the urn along with the ashes (*ossilegium*) (Erasmo 2008).

Changing Patterns of Cremation and Inhumation in the Roman World

Ancient texts indicate that inhumation was the standard method of disposal of the dead in pre-Roman Italy and that the practice of cremation slowly gained popularity between the fourth and first centuries BCE (Graham 2006). This burial custom was not universally adopted throughout Roman Italy and there is archaeological evidence that inhumation remained the predominant practice among local populations in southern Italy, possibly linked to the influence of Greek colonies and their burial practices in the region (Davies 1977). The persistence of inhumation may also have been related to the retention of indigenous cultural practices in response to Roman expansion, or it may simply have been due to financial considerations and the reportedly lower cost of inhumation. Cremation remained the predominant custom in urban centers such as Rome from the first century BCE through the second century CE, but beginning in the second century CE, inhumation regained popularity and became widespread across the Roman Empire (Graham 2006; Hope 2009). Recent explanations for the shift from cremation to inhumation after the second century CE have discounted the idea that this was linked to the spread of Christianity and was more likely the result of changing patterns in burial display and commemoration (Morris 1992; Graham 2006; Bodel 2008).

The Burial of Infants and Children

Writers from the Roman period advised parents to be stoic about the loss of very young infants since they were not yet fully integrated into Roman society. Infants less than 40 days old were to be buried in or around domestic buildings and those under the age of 6 months could not be cremated, although the assertion that Romans did not provide young infants with proper burials is not supported by archaeological evidence from

Burial Practices and Tombs in the Roman World, Fig. 2 Libation burial with two curved imbrices inserted vertically in the soil above the burial cover

around the Roman world (Carroll 2011, 2018). Archaeological and epigraphic evidence indicate that infants under 1 year of age are underrepresented in cemeteries from the Roman period, but this does not necessarily reflect a lack of concern or grief over the loss of a child (Hope 2009; Carroll 2011). Preservation of infant remains and the ability to recognize and recover the bones of young children may also contribute to the underrepresentation of infants in the archaeological record (Norman 2010; Carroll 2011). The commonly held view that the funerals of infants and children were held at night, due to the association with death pollution and due to their marginal status in society, has recently been challenged (Carroll 2018). Infants were sometimes buried in broken amphorae, interpreted as symbolic of the infant's return to the womb (Norman 2010). Older children were cremated or buried in a similar manner to adults and there are proportionally more funerary epitaphs to children over the age of 1 year, possibly reflecting the increased emotional investment of the parents in older children and the public expression of grief over the loss (Hope 2009). A recent survey of archaeological evidence for infant burials in the Roman world reveals considerable variation in the location of their graves both within cemeteries and settlements (Carroll 2018).

Maintaining Relationships with the Dead

The relationship between the living and the dead did not end after the burial rituals. There was an ongoing connection between the living and the dead, consistent with the belief that the spirits of the dead could affect the living and that it was the responsibility of surviving family members to maintain the burial or tomb. Regular visits to the grave would occur throughout the year to commemorate birthdays and the anniversary of the day the person died. The Roman festival of *Parentalia* (13th–21st of February) was held annually to honor the deceased members of the family. Food and wine (libations) would be offered at the grave site to share with the deceased, often through the presence of libation tubes inserted in the ground above the burial (Fig. 2), or food could be left on potsherds or at small altars at the grave site (Dolansky 2011). The consumption of food at the grave site is further attested archaeologically by the presence of dining benches inside or outside communal tombs, such as those found at the necropolis of Isola Sacra near the Roman port city of Ostia (Fig. 3). The festival of *Lemuria* took place on the 9th, 11th, and 13th of May each year when restless spirits returned to their homes and rituals were performed by the patron of the house to make the spirits leave. Burial was also a means of commemoration, and so tombs were not only for the dead but were also competitive expressions of status for the living to witness as they passed by.

Burials and Tombs

Single Burials

Simple inhumations – Poorer members of society were likely buried in simple pits in the ground or

Burial Practices and Tombs in the Roman World, Fig. 3 House tomb with two benches (*biclinia*) for funerary banquets flanking the main door

in a burial container like a wooden coffin. The location of these burials may have been unmarked or indicated with a grave marker that could vary in size and permanence. Sometimes stone *stelae* marked the location of the burial, or more elaborate funerary altars were placed over the burials that were designed to resemble a sacrificial altar (Hope 2009). Fragmentary amphorae were sometimes reused in burial contexts to mark the location of a burial in a cemetery and also to act as libation tubes, such as those found outside the monumental tombs at the necropolis of Isola Sacra near Rome (Fig. 4).

Cappuccina burials – This was a common burial structure found throughout the Roman world in which the deceased would be placed in a simple pit or laid out on a series of large flat roof tiles (*tegulae*). The deceased was then covered by a series of paired *tegulae* inclined over the body in an inverted "V" shape, with the narrowest part of the burial at the top (Fig. 5). The ridge formed by each pair of tiles would sometimes be capped with curved tiles (*imbrices*) or fragments of pipe. The burial would then be partially or completely covered with soil.

Libation burials – Not all burials possessed libation tubes, but when present, they were simple pit burials, sometimes covered with a series of

Burial Practices and Tombs in the Roman World, Fig. 4 Amphora burial from the Roman necropolis of Isola Sacra

Burial Practices and Tombs in the Roman World, Fig. 5 Cappuccina burial from the Roman cemetery at Vagnari, south Italy

horizontal *tegulae* and a terracotta tube or two *imbrices* were inserted vertically in the soil above the burial (Fig. 2). Cappuccina burials could also have libation tubes inserted into the soil above the grave.

Sarcophagi – Stone boxes with flat or gabled lids that were often elaborately carved with biographical scenes of the deceased, mythological scenes, hunting scenes, or representations of military conquests on the exterior, but the interior was usually left undecorated. This type of burial container gained popularity among wealthier members of society with the shift from cremation to inhumation in the second century CE and was usually placed inside larger monumental tombs (Morris 1992).

Cassone – Barrel-vaulted brick structures built directly above single inhumation or cremation burials, examples of which are found in the necropolis of Isola Sacra and the Vatican necropolis in Rome (Graham 2006).

Multiple Burials

Puticuli ("little pits") – There are a small number of references in ancient texts to the existence of mass graves outside the Esquiline gates in Rome that were used for the disposal of slaves and poorer members of society. Excavations in Rome by Rodolfo Lanciani in the nineteenth century reportedly revealed the presence of "hundreds" of these pits containing human and animal remains, although the archaeological evidence for these estimates has been called into question (Graham 2006). A critical examination of the archaeological and literary evidence reveals that the Esquiline pits were only used for a short period of time (i.e., between the third and second centuries BCE) and were likely not used as a normal mode of disposal for the poor in the city of Rome, but rather may have been associated with epidemics or other catastrophic events (Patterson 1992; Graham 2006). Horace refers to the presence of a graveyard scattered with bones on the Esquiline hill, which was eventually covered over by gardens in the first century BCE and may have been a cemetery for poorer members of society (Morris 1992; Bodel 2000). It has been suggested that cremation in public crematoria became the common mode of disposal of the urban poor during the Imperial period (Bodel 2000; Patterson 2000).

Columbaria – Communal tombs containing a series of niches intended to hold cremation urns (*cineraria*) that gained popularity in the first

Burial Practices and Tombs in the Roman World, Fig. 6 Interior wall of a tomb at Isola Sacra showing a series of niches for cremation urns

century BCE and stayed in fashion through the second century CE (Morris 1992; Bodel 2008). *Columbaria* varied in size, from small family tombs (Fig. 6) to larger structures that contained hundreds of niches and could be built above or below ground. These communal tombs could contain members of the patron's extended family, along with household members including slaves, freedmen, and their descendants (Patterson 2000). Funerary societies, called *collegia*, also existed to provide less wealthy members of society a means to ensure a proper funeral through regular payments to the society, which guaranteed that members would be interred in communal *columbaria* upon their death (Toynbee 1971). These funerary clubs did not, however, replace the role of the family in the proper disposal of the dead but acted in cooperation with the family to guarantee a proper funeral and final resting place (Patterson 2000; Bodel 2008).

Catacombs – A form of subterranean collective burial in ancient Rome that gained popularity in the second century CE, following the gradual shift in burial practice from cremation to inhumation. This period also coincides with the emergence and spread of Christianity in the Roman world, but catacombs were not originally a Christian phenomenon and likely developed from earlier forms of subterranean burial chambers called *hypogea* (Morris 1992; Bodel 2008). The catacombs discovered outside the city of Rome are characterized by complex subterranean tunnels carved into the volcanic rock with niches lining the walls (*loculi*) for individual interments and the presence of larger chambers (*cubicula*). According to Bodel (2008), the criteria for identifying catacombs are independent entrances at ground level, space for large numbers of inhumations, and the capacity for extension of existing galleries to accommodate further burials.

Monumental tombs – The size and structure of monumental tombs varied according to the tastes and wealth of the owners, the competitive expression of social status, and changing fashions in commemoration. Masonry-built tombs varied in appearance from simple open-air tomb enclosures to a wide variety of tomb structures including houses, towers, temples, and pyramids (Toynbee 1971; Hope 2009). From the first century BCE through the second century CE, these communal tombs were in fashion, and the tombs of elite members of society often lined the main roads outside the city. Tombs from the Republican period were mainly constructed for members of the immediate family, but in the Imperial period they included members of the extended family, their slaves, and freedmen (Patterson 2000).

House tombs, like those found at the necropolis of Isola Sacra near Ostia, are rectangular roofed structures with doorways, windows, internal decoration (e.g., mosaics and frescoes), and some with benches for funerary banquets (Hope 1997). Earlier tombs contained small niches for funerary urns, consistent with the preference for cremation up to the second century CE, while later tombs also contained spaces in the walls for inhumations (*arcosolia*) and others contained spaces underneath the floors (*formae*) for additional burials.

According to Toynbee (1971), circular tombs found in Roman Italy likely developed from the Etruscan tumuli found near Rome. The most famous example of a circular tomb is the mausoleum of Augustus located in the Campus Martius in Rome, characterized by a series of concentric walls surrounding a central chamber. The structure was covered by an earthen mound and a statue of Augustus was on the top of the mound (Toynbee 1971; Hope 2009). Other famous examples of circular tombs include the tomb of Caecilia Metella, the *tomba rotunda* of Lucilius Peto, and the mausoleum of the emperor Hadrian, more commonly known as Castel Sant'Angelo.

International Perspectives

Systematic and comprehensive excavation of urban and rural cemeteries found on Roman period sites will help to identify variability in patterns of burial and commemoration. In addition, better integration is needed between epigraphic evidence (when present), the analysis of burials and their contents, and the osteological analysis of the people buried within. Excavation and analysis of burials should be undertaken by archaeologists and bioarchaeologists who are trained in the identification of human remains, particularly the recognition of small, delicate infant remains, so that the maximum amount of information can be obtained from each burial. This will help to provide a more nuanced understanding of differences in burial treatment and attitudes toward the dead based on variables such as age, gender, and health (e.g., Gowland and Redfern 2010; Prowse 2011). Recently, Graham (2018) has called for a more deliberate examination of sensory experiences related to the physical landscape of Roman cemeteries.

B

Future Directions

Much of what we know about the burial practices and tombs in the Roman world comes from literary evidence and monumental tombs associated with large urban centers like Rome and Pompeii. What ultimately happened to the enslaved and poor after death is not well known, particularly with respect to the existence and role of *puticuli*, and what we know about these mass graves is cited mainly from one nineteenth-century source. Continued research on the burial treatment of traditionally underrepresented members of Roman society (i.e., women, children, slaves, rural populations) will contribute to a greater understanding of burial practices and commemoration of different segments of ancient Roman society.

Burial Practices in Europe

Ariane Maggio
University of Western Australia, Crawley, WA, Australia

Introduction

Burials can provide a wealth of information on a society (Tarlow and Stutz 2013). This is not only through the anthropological assessment of any human remains present in the burial but also through the interpretation of the factors behind the treatment and burial of the dead. Accordingly, the burial practices of any given society can provide information on societal status, cultural customs, and religious or spiritual belief systems (Pearson 2003). In Europe, people have been burying their dead since the Paleolithic period, with the earliest undisputed intentional burial in Europe at the Neanderthal site of Krapina in Croatia, dating back to approximately 130,000 years ago (Russell 1987). Furthermore, the types of burials are highly variable across Europe, ranging from simple grave burials to elaborate monumental tombs containing the burials of multiple individuals.

Definitions

In this entry "burial" refers to the act of interring the remains of a deceased individual either within the ground or above ground in a structure designed to house the remains, such as a tomb. In this entry the term "burial practices" is used to refer to any practices or activities related to the burial of the dead, such as a religious funerary rite, or how the dead were buried. The term "grave" is used to refer to an underground burial that does not involve interment in a burial structure, such as a tomb.

Key Issues

Factors that Influence the Treatment and Burial of the Dead

There are a number of factors which can influence the treatment and burial of the dead in any given society; these range from practical concerns regarding decomposition to cultural practices, societal status, and spiritual or supernatural beliefs (Pearson 2003). From a practical standpoint, the burial of the dead was one way of combatting the unpleasant effects of bodily decomposition. Burials removed the smell of the decomposing body from the living space, with the secondary effect of reducing the ability of the body to attract carrion animals and insects (Pearson 2003). However, it is important to consider that a burial is limited by the availability of burial space. In dense urban environments, this can be a particular challenge.

In some cultures, such as the Romans, there was also the belief of "death pollution," whereby the living could be contaminated by the dead (Hope 2000). By burying the dead, and by cleansing themselves of traces of death, the living would no longer be seen as at risk of being polluted by death. There were also those who believed that some part of the dead would continue to exist after death and impact the living if proper burial practice was not completed. In some cultures this fear of the dead affecting the living manifested in a fear of the dead rising from their graves to terrorize and cause harm to the living and led to specific burial practices to combat the perceived risk (Murphy 2008, see "Aberrant Burials" below).

Burials can also be a marker of the status of the deceased individual(s) within society, with elaborate burials and rich grave goods typically interpreted as an indicator of the buried person being of the elite or having favored status (Conneller 2013). In particular, the cost of the

construction of elaborate or large burial monuments or the effort required for the burial could indicate elite specific burials. Grave goods, the materials the individual was buried with, could include everything from weaponry, pottery, jewelry, animal bone, animals, and boats to chariots (Pearson 2003). By comparison, burials of lower-class individuals were generally simpler and less elaborate. However, this is dependent on the context, and it is important to note that a simple burial may not be indicative of lower status if that society did not practice elaborate burials as a rule.

Finally, burials can also be influenced by, and show evidence of, some manner of religious or spiritual belief. This can be shown through the inclusion of particular grave goods, the patterns of burial, and the positioning of the body relative to monuments, cardinal directions, or astrological features (Pearson 2003). Even the manner of burial can provide information regarding the beliefs and customs of a particular group. For example, the Christian Church espoused the idea of bodily resurrection, and given that cremation reduced the body to fragments of bone and ash, it was not practiced by a large majority of Medieval Christian Europe (Brennan 2014).

Cremation vs. Inhumation

There are two broad types of burial present in the archaeological record: cremation burials and inhumations. Cremation burials are those where the body of the deceased has first been burnt, usually on a pyre, and the remaining bone fragments and ash have been collected for subsequent burial or for internment within a burial structure (McKinley 2013). In contrast, inhumation refers to burials where cremation has not occurred. Both involve effort on the part of those performing the burial: as for an inhumation a grave must be dug or a burial structure to house the dead constructed, whereas for cremation, a pyre or crematorium must be constructed, and the body must be burnt until all that remains is fragments and ash (McKinley 2013).

Examples of Burial Practices in Europe

Burials can involve either a single individual or multiple individuals. They can involve the burial of the deceased below ground or burial via interment in a burial structure. The following parts of this entry will provide a brief overview of the burial practices that have been documented in Europe. It is important to note that the burial practices of Europe span both a large temporal period and geographic space, and thus not all iterations of burials will be covered here. In addition, some burials are an amalgamation of multiple types of burial practices; thus there may be significant overlap between the ostensibly already broad categories.

Simple Inhumations

Simple inhumations involved the burial of the dead in a grave. A grave is used in this entry to refer to an underground burial where the deceased is placed directly in the ground rather than in a tomb. Grave burials can include both coffins and grave goods, but do not relate to burial in a tomb structure. Simple inhumations have been used since our ancestors first began to bury the dead, either through digging a grave or from repurposing natural features such as depressions in cave floors and subsequently covering the dead placed within them (Riel-Salvatore and Gravel-Miguel 2013). The term mass grave is used to refer to a single burial containing multiple individuals, who typically died at or about the same time. A site containing multiple burials, such as a cemetery, is not a mass grave unless those individuals were buried in the same grave. Mass grave inhumations are commonly the result of violence (such as war) or a pandemic illness (such as the plague).

Coffins, Cists, and Sarcophagi

These burials involve the placement of the deceased individual in a sealed physical structure for burial, either above or below ground. Coffins (alternatively known as caskets) are rectangular or six-sided elongated boxes with a

lid, in which the deceased are placed for burial (Colman 1997). They are most commonly made of wood and are buried below ground in cemeteries, although they can be present in tombs. Cists are small stone-built boxes, which can contain the bodies of the dead or their cremated remains (Cunliffe 2001). Cists can be found on their own or in association with burial mounds and other monuments.

Sarcophagi are rectangular boxes typically made of stone and like a coffin serve to hold the body of the deceased (Toynbee 1996). They can be located above ground as a freestanding monument, within churches, inside burial structures such as burial mounds or tombs, or buried below ground. Sarcophagi were used in Ancient Greece and Rome, up until approximately 500 CE where they fell out of favor in Christian Rome (Toynbee 1996). However, they continued to be used for the burial of elite figures in Christian Europe, such as rulers or important members of the clergy.

Catacombs and Crypts

The term catacombs refers to underground burial complexes, sometimes referred to as cities of the dead or necropolis. These spaces include passages and galleries, often with recesses for graves to be dug or for the placement of tombs, sarcophagi, or funerary urns (Toynbee 1996). The most famous of these in Europe are the Catacombs of Rome, which date back to 200 CE and comprise at least 40 separate burial complexes and include multiple religious groups (Toynbee 1996). These are located outside of the ancient Roman walls of the city, as the law of that period forbade burial within the city limits.

A crypt is typically a form of tomb, which is usually located beneath the floor of a church, but also other buildings (Colman 1997). Within the crypt, the deceased were often buried in coffins or sarcophagi. In more modern usage, crypts are also found in cemeteries and under churches and chapels, but they can also be found on private estates below mausoleums or private chapel buildings.

Monumental Burials

There are a number of different types of monumental burial practices in Europe, many of which are used in conjunction with one another or are present within the same culture and time period. Monumental burial practices refer to burials involving a large construction or monument of some form, which can be made of earth and/or from wood and stone.

Tombs (Including *Mausoleums*, *Tholoi*, and *Dolmens*)

The term tomb is used here to refer to an enclosed interment space or burial chamber that has been constructed for the burial of the dead. These can be located above or below ground, within other burial structures, such as below churches (see Catacombs and Crypts above), and can include burials in coffins and sarcophagi. Forms of monumental tombs include passage tombs, mausoleums, tholoi, and dolmens.

A passage tomb typically consists of a narrow stone passage which leads to one or more burial chambers (Scarre and Laporte 2015). As they are typically covered with stone or earth, they are usually associated with burial mounds (see Burial Mounds below).

In contrast an external free-standing building which encloses the interment space or burial chamber of a deceased person or people is known as a mausoleum. A mausoleum can be considered a type of tomb, but often the tomb can be located within or beneath the mausoleum (Colman 1997). Mausoleums are a constructed monument to the deceased which can be found both in cemeteries and on private estates and are often a marker of the status of the buried individual or their family. Historically, mausoleums were used by leaders, such as is the case with the Mausoleum of Augustus, wherein the ashes of the Emperor and the imperial family were interred (Davies 2010). However, smaller mausoleums later became in fashion for the nobility and the gentry.

A tholos (plural tholoi) is a beehive-shaped burial tomb which typically contains more than

one burial, either in pits or in cists, with an entrance passage (Cunliffe 2001). These tombs are characterized by their domed roofs, which were commonly constructed of mudbrick or stone. After burial the entrance to the tomb would be covered over, leaving most of the tomb underground. In Europe, tholoi are commonly associated with Greece, and in particular the Mycenaean culture. The Lion Tholos Tomb at Mycenae was constructed between 1400 and 1300 BCE and was approximately 14 m in height, prior to the collapse of the domed roof (Cunliffe 2001).

A dolmen is a single chamber tomb usually consisting of vertical megaliths and a large flat capstone, which forms a table shape (Scarre and Laporte 2015). Dolmens predominately date to the early Neolithic period, around 4000–3000 BCE, and may have been covered by earth or stone tumuli which have subsequently eroded away over time (Scarre and Laporte 2015). Dolmens can also mark the entrance to a passage tomb.

Burial Mounds (Also known as *Tumuli*, *Kurgan*, *Barrows*, *Cairns*)

Monumental burial mounds are common across Europe (Cunliffe 2001). The term burial mound is used here to refer to those burials which are covered by a large constructed mound of earth or stones. They can be a variety of shapes from round and hill shaped to rectangular mounds (Fokkens and Harding 2013). Burial mounds are known by a plethora of names, including tumuli, kurgan, barrows, and cairns. The terms tumulus, kurgan, and barrow can often be used interchangeably and generally depend on the place in Europe the mound is located; tumulus is the Latin term, while kurgan is the standard term in Eastern European archaeology, and barrow is more commonly used in Anglo-Saxon contexts (Fokkens and Harding 2013). The term cairn however refers to a human-made pile of stones, and in this context it covers a burial. Cairns can be a marker of a grave site, cover the entirety of a passage grave, or cover a single burial chamber (Scarre and Laporte 2015). Burial mounds may also include tombs, passage graves, urn burials, single inhumation burials, ship burials, and mass graves, in any combination (Cunliffe 2001). The site of Sutton Hoo in Great Britain is one such site that contains burial mounds in connection with multiple other forms of burial (Carver and Evans 2005). In one mound at Sutton Hoo, there is a famous ship burial (see "Ship Burials" below), but in other contemporary burial mounds at the site, there are inhumations and cremation burials (Carver and Evans 2005).

Ship Burials

Ship burials are another form of monumental burials, commonly associated with Scandinavian and Anglo-Saxon culture and in particular the Vikings (Fokkens and Harding 2013). Smaller ship graves are also known as boat burials. This form of burial most commonly involves the burial of a ship as a grave good along with the body of the deceased. Typically, the ship or boat is used to hold the body or bodies of the deceased and any grave goods, but it can also be included within the burial alongside the body (Fokkens and Harding 2013). These burials are usually found within earthen burial mounds or are covered by stone cairns. Less commonly, ship burials can also take the form of ship without the physical boat being present in the grave, through boat-shaped mounds or through stone markers laid out in the characteristic shape of a ship (Fokkens and Harding 2013).

Urn Burials

Cremation Burials

As mentioned earlier, cremation burials are the burial or interment in a burial structure of the cremated remains of the deceased individual (s) (McKinley 2013). These may also be associated with monumental burials and burial mounds. The Urnfield culture from 1300 to 750 BCE central Europe is named thus due to its association with large cemeteries of urn cremation burials (Cunliffe 2001). Cremation was outlawed in parts of Europe during the Middle Ages because of the then prevailing Christian belief that it would hinder bodily resurrection, although it was used by the Church as a punishment for heretics

(Brennan 2014). The practice of cremation was later reinstated in the modern era in part due to concerns regarding space in urban environments and concerns regarding disease transmission.

Urn Inhumations

Urn inhumations refer to the burial of the deceased within an urn or another form of pottery, such as an amphora (Tarlow and Stutz 2013). These urns would then be buried, in a manner similar to sarcophagi or coffin burials. These were used in both ancient Greece and Rome for the burial of infants, where the urn would be altered and the remains of the child placed in the urn prior to it being resealed and buried (Grubbs et al. 2013). The Kylindra cemetery site on the island of Astypalaia in Greece is an example of this style of burial. Excavation of this cemetery, which dates to between 800 and 400 BCE, uncovered thousands of urn burials which when examined were found to be the burials of infants (Shepherd 2013). These burials generally do not contain any grave goods.

Aberrant Burials

"Vampire" Burials

The so-called vampire burials of Europe are a form of burial practice where the body of the deceased was treated in a particular way due to a fear of their corpse reanimating and causing harm to the living (Murphy 2008). It was not necessarily thought that the dead would drink the blood of the living, as is the modern vampire mythos of today, but that they might spread disease or generally cause harm to the living if they were able to escape their grave (Murphy 2008). Accordingly, the burial customs for individuals suspected of being able to reanimate include removing the head of the deceased and burying it at their feet, removing their lower limbs so they could not walk, placing bricks or stones in their mouths to prevent them from being able to bite, pinning them to the base of the grave so they could not rise with a metal rod through their chest or stones on top of their body, or by placing a bladed tool at their neck so they might decapitate themselves if they tried to sit up (Betsinger and Scott 2014). It is thought that these burials were a fear of a malignancy of some sort, be it that the individual was an outsider, had a physical abnormality, or had died of mysterious illness that could not be understood and that the community feared they would spread to the living (Betsinger and Scott 2014).

Bog Burials

Although not traditionally considered a burial, the deliberate placement of deceased individuals within peat bog can be seen as an act of burial. In bog burials, the deceased were placed in the peat bog, some with sticks or stones to hold their bodies down (Van Der Sanden 2013). Under the right conditions, the chemical composition of the peat bog acted as a preservative and would mummify the remains of the deceased. Most of the bog bodies that have been recovered from the bogs in Europe date from the Iron Age (Van Der Sanden 2013). Many bog bodies show signs of execution, in the form of stab wounds, beheading, signs of strangulation, or evidence of blunt trauma. It is widely thought that these burials were forms of human sacrifice and thus give evidence of a shared or similar spiritual belief across Iron Age Europe (Van Der Sanden 2013).

Future Directions

The various types of burials in Europe have been studied by many archaeologists from various schools of thought and subdisciplines. However, the burial record in Europe spans a long time period and many different cultural groups. While much of our information on burials during the historical period comes from contemporary sources, as is the case with Roman burials, there are no written records for burials from pre-history, and often even the records from the historical period are lacking. It would be interesting to see more reconsideration of previously excavated sites and material from different types of burials in light of the recent advances in archaeological science and technology, particularly in relation to monumental burial mounds.

Burke, Heather

Claire Smith and Jessica Lowther
College of Humanities, Arts and Social Sciences, Flinders University, Adelaide, SA, Australia

Basic Biographical Information

Heather Burke (Fig. 1) is a Professor in archaeology at Flinders University, South Australia. She received her Bachelor of Arts with First Class Honours from the University of New England, Australia, in 1987. She studied for her Ph.D. under the supervision of Iain Davidson and Graham

Burke, Heather, Fig. 1 Heather Burke with a site visitor, 2015, Port Lincoln, South Australia. (Photo: Lynley Wallis)

Connah and was awarded the Doctor of Philosophy (Archaeology) from the University of New England in 1997.

Dr. Burke is an historical archaeologist with a wide range of research interests, including the construction of class and status through material culture, the archaeology of cross-cultural engagement, and the links between cultural heritage and contemporary social identity.

After gaining her first qualification, in 1988, Dr. Burke started her archaeological career as an Acting Archaeologist for the NSW National Parks and Wildlife Service. After that she became a tutor with the Department of Archaeology and Paleoanthropology at her alma mater, the University of New England, from 1988 to 1991. She worked throughout New South Wales, the Northern Territory, and Queensland, serving as an Assistant Regional Archaeologist for the NSW National Parks and Wildlife Service (1990–1991), a Private Archaeological Consultant (1991–2000), and a Senior Archaeologist for Gordon Grimwade & Associates, Yungaburra (2000–2002). Dr. Burke joined the Department of Archaeology at Flinders University in South Australia in 2002.

Many of Dr. Burke's projects are initiated by the communities with whom she works. Dr. Burke's professional and community engagement projects show her passion for these research interests and have included excavations at historical archaeological sites in Adelaide, Port Lincoln, and Mallala, South Australia, at Willow Court in the Royal Derwent Hospital Tasmania (Auld et al. 2019) and on Native Mounted Police sites in Queensland (Burke et al. 2018b). Her excavations have provided communities with valuable information about their local history and archaeology and numerous students with meaningful learning experiences.

Dr. Burke's commitment to her students and their future careers is renowned. Her dedication to her teaching profession has been recognized in several awards, most notably the Flinders University Vice Chancellor's Award for Teaching, Flinders University, Team Category, with Claire Smith, in 2003, and the national Carrick Award for Teaching Excellence, Team Teaching, in 2004.

Major Accomplishments

Dr. Burke's accomplishments in archaeology lie in three areas: in her research as a theoretically sophisticated and community-oriented historical archaeologist; in service to her profession through administrative roles, such as editing and conference convening, that have allowed peers and young scholars to flourish; and in her contributions as an outstanding teacher, who has developed world-leading graduate programs in professional archaeology (Fig. 2).

Dr. Burke's research publications on the links between style, class, and identity have made major theoretical contributions to underrepresented and under-theorized areas of historical archaeology. Her authored book *Meaning and Ideology in Historical Archaeology* (Burke 1999) undertook landmark investigations of the

Burke, Heather, Fig. 2 Heather Burke recording a Native Mounted Police camp site in southeastern Queensland (July 2019). (Photo: Lynley Wallis)

construction and maintenance of capitalist ideologies in rural Australia:

> The theoretical sophistication of the study is admirable, and it should serve as a model for research in other parts of the world . . . The study of capitalism challenges archaeologists and thus it is impressive when a scholar successfully rises to this challenge. *Meaning and Ideology in Historical Archaeology* meets this challenge and should be read by any scholar interested in understanding capitalism. (McGuire 2001: 172–173)

Dr. Burke has conducted significant research on identity and ethnicity in South Australia, most recently with her doctoral student, Susan Arthure (see Burke et al. 2018a). She also publishes in the areas of Indigenous contact and social archaeology (e.g. Burke et al. 1994; Smith and Burke 2006). The edited volume *Kennewick Man: Perspectives on the Ancient One* (Burke et al. 2008) redressed a lack of Indigenous views on one of the most contentious topics in modern archaeology in the United States. This book canvassed a range of responses from Indigenous and non-Indigenous archaeologists, judges, anthropologists, tribal elders, students, and specialists over the landmark legal struggle for control over one of the oldest skeletons in the US Pacific Northwest.

Dr Burke has made a major contribution to post-colonial archaeology (e.g. Smith and Burke 2010). She has been a Chief Investigator on ten grants awarded by the Australian Research Council. Her most recent major project is the ARC Discovery project "The Archaeology of the Queensland Native Mounted Police," a multi-institutional project between Flinders, the University of Southern QLD, and the University of Notre Dame Australia. This research focusses on the Australian colonial "frontier" and its social and material effects. In 2018 this project was profiled in "Making a Difference," the ARC's annual publication, and was one of only six projects invited by the ARC to present directly to ARC leadership and Federal Government ministers. A major outcome is an online database containing all of the archaeological and historical data collected during the project. This will be

Burke, Heather, Fig. 3 Heather Burke excavating with Mardi Reardon-Smith and Cherrie de Leiuen. Trench 16, Boralga, 2018. (Photo: Lynley Wallis)

launched as a public resource in December 2019. For archaeologists it contains complete data sets from five excavated sites, while the raw information has been developed into resources for secondary school teachers across QLD who are now required to teach elements of the Frontier Wars. The blog associated with this project (https://archaeologyonthefrontier.com) was selected by the National Library of Australia to be archived as part of the Pandora Archive, which itself was placed on the UNESCO Memory of the World Australian Register in August 2004 (Fig. 3).

Dr. Burke's contributions to her profession are evident in the administrative and organizational roles she has held within her career. These roles can be roughly divided into conference organization and editorship. Dr. Burke's conference organization includes being Program Chair for the Fifth World Archaeological Congress (WAC-5), held in Washington, DC, in 2003; the 1997 Fulbright Symposium ("Indigenous Cultures in an Interconnected World"), at the Museum and Art Gallery of the Northern Territory, Darwin, 1997; the "Women in Archaeology" conference at the University of New England, NSW, Australia; and the World Archaeological Congress symposium "Cultural Heritage and Intellectual Property Rights," held in 2006 in Burra, South Australia. Her service to the profession includes having been Co-editor of *Australian Archaeology*, the journal of the Australian Archaeological Association (2012–2015), and being Associate Editor (Australia and New Zealand) of *Historical Archaeology* (2016–present).

Dr. Burke's teaching is characterized by intelligent innovation. These include the development by undergraduate classes of online and community accessible databases that provide a unique source of primary information for the wider community that exists nowhere else and experiential learning through role-playing as archaeological theorists (see Smith and Burke 2005) and elegant Victorian era tea parties. Dr. Burke's major publication in relation to teaching innovation is the edited volume *Archaeology to Delight and Instruct* (Burke and Smith 2007). This volume took Horace's philosophy that the purpose of literature is to "delight and instruct" and applied it to the teaching of archaeology at a tertiary level. The contents explore ways to integrate the formal process of teaching archaeological theory with the potential to have fun in a university classroom.

Dr. Burke's commitment to ensuring standards of excellence in the field practice of archaeology has manifested in two ways. The first is through her publications, notably *The Archaeologist's Field Handbook* (Burke et al. 2017), which provided

the first comprehensive field manual for archaeologists in Australia in almost 20 years. As a discipline, archaeology has long been fractured by the idiosyncratic use of concepts, definitions, and methods between practitioners influenced by different training regimes, specific histories of practice, and the varied requirements of different state authorities. This book set out to establish minimum standards to address this problem while also maintaining flexibility in adapting such standards to the specific circumstances encountered in tackling large and small problems. It has been adopted by universities as a textbook nationally and internationally and by state agencies seeking to regulate the practice of consultants in the archaeological and cultural heritage industries and has been incorporated into the Australian version of the Skills Passport developed by the Australian National Committee for Archaeology Teaching and Learning. In 2005, the first edition of *The Archaeologist's Field Handbook* won the White Bequest Award from the Australian Academy of the Humanities. The success of this manual was furthered in an international context through regionally specific editions, published for the United States (Burke et al. 2009) and Spain (Domingo Sanz et al. 2007).

The second way in which Dr. Burke has engendered high standards in field archaeology has been in her role as former Head of the former Department of Archaeology at Flinders University in the development of a Master of Archaeology and a Master of Cultural Heritage Management. These programs are embedded with industry partners and have provided unprecedented industry-engaged training for cultural heritage practitioners. They have become the premier graduate training programs in Australia.

Dr. Burke is a community archaeologist with a serious commitment to engaging the academy with industry and community groups so that the advantages of a university system can also benefit wider society. Her success in archaeology, commitment to her students, and contributions to the field of archaeological education in Australia are inspiration to her students at Flinders University and of great benefit to the communities with whom she has worked during her archaeological career.

Burned Remains in Forensic Contexts

Scott Fairgrieve
Department of Forensic Science, Laurentian University, Sudbury, ON, Canada

Introduction

Burned human remains may be found in a variety of contexts (Fairgrieve 2008, 2010; Schmidt and Symes 2008). Such remains recovered from a "forensic context" have relevance to a legal inquiry as do cases where a death is suspicious must be investigated. In many countries, legislation is in place which states that any death that is not attended by a physician must be investigated (e.g., in the Province of Ontario, Canada, see the Coroner's Act; RSO Coroner's Act 2002 c. C.37, s.31). Under such an investigation the investigative authorities attempt to answer the following five questions:

1. Who the deceased was?
2. How the deceased came to his or her death?
3. When the deceased came to his or her death?
4. Where the deceased came to his or her death?
5. By what means the deceased came to his or her death?

Burned skeletal remains may be difficult to locate, recover, analyze, and interpret. For example, remains associated with mass disasters, such as plane crashes, train derailments, domestic fires, and even automotive collisions, are often highly fragmentary, and commingled with other individuals and other items at the scene. The recovery, documentation, and identification of these remains may provide further evidence of the cause of death and have serious implications for the interpretation of the scene. A multidisciplinary approach to the processing of these scenes is without question the best practice.

Burned remains may be found in clandestine contexts. The use of fire to dispose of remains is not a new concept. It has been practiced in a variety of cultures over thousands of years (Fairgrieve 2008). Given enough fuel and time, a perpetrator may eliminate all of the soft tissue leaving only bones and teeth. This material may be intentionally broken and crushed in order to fragment the remains further. These remains may be subsequently moved to another location or buried.

The discovery and recognition of burned human bone is clearly a challenge, regardless of the context. There are many issues when it comes to processing such scenes. It is necessary for the forensic anthropologist to have a clear understanding of how bodies burn and how various soft and hard tissues are altered by fire. Hence, precautions regarding the recovery, documentation, and understanding the limits of an analysis are outlined below.

Key Issues

Burning of Soft and Hard Tissues

Fire consists of heat and light that is generated by an oxidation reaction (DeHaan 2002). This process, known as flaming combustion, is the gaseous combination of a fuel (tissues of the body) and an oxidizer (oxygen). Although the full mechanics of how fuel, heat, air (oxygen), and an uninhibited exothermic chemical chain reaction all combine to result in a sustained combustion reaction is beyond the scope of this entry, it is sufficient to note that there is a chemical breakdown (pyrolysis) of the molecular structures of a fuel that results in the production of vapor, gases, and a residual solid (char). The heat converts the mass of the fuel into a form that can be ignited and

a sustained combination may ensue if appropriate proportions of oxygen are present.

The combustion of a human body is not an even process. A body consists of soft tissues of varying thickness and densities over bone. Therefore, some areas with bones closer to the surface, such as the neurocranium, will have the soft tissue eliminated prior to that of the abdominopelvic cavity. In general, the tissues of a body pass through the clinically defined degrees of burning (e.g., 1st through to 5th degree burns). When the burning process has proceeded to the point at which bone is being burned directly, such burns are said to be either fourth degree or fifth degree (DeHaan 2002). Prior to this state the superficial layers of the skin initially blister (a separation of the epidermis from the underlying dermis). The layers of skin contract due to the dehydrating action of the fire. Large fissures open in the skin, exposing the fatty hypodermis. With the consumption of fat, muscle is then directly charred and burned. The heating of the muscle tissues causes a contraction, and the larger flexor muscles overpower the typically smaller extensor muscles resulting in the flexion of various joints of the body, particularly in the appendages and the posterior of the neck. The bending of the arms and the fingers of the hands are said to mimic the stance of a boxer, referred to as the "pugilistic pose."

The clinical scale for degrees of burning is not sufficient for describing the state of burned human remains in forensic contexts. The Crow-Glassman Scale (CGS) remedies this situation and reflects a systematic pattern of burning (Glassman and Crow 1996) (see Table 1 below for the full scale).

The differing levels of the CGS also serve to describe the inherent difficulties in processing scenes with burned human remains. These range from the recognition of the remains to the collection of bones and teeth when a body has reached CGS 5. The CGS also reflects the fact that the body does not burn evenly. The head and the appendages will burn and eventually fall away from the body after having assumed the pugilistic

Burned Remains in Forensic Contexts, Table 1 The Crow-Glassman Scale (CGS) of burn injury to human remains (Glassman and Crow 1996)

CGS level	Description
1	Burn injuries characteristic of typical smoke death. The body may exhibit blistering of the epidermis and singeing of the head and facial hair. Recovery of the body is similar to that for other victims not involving burn injury. The body is recognizable for identification at this level
2	The body may be recognizable, but most often it exhibits varying degrees of charring. Further destruction of the body is limited to the absence of elements of the hands and/or feet, and possibly, the genitalia and ears. Additional search near the body is warranted for recovery of the disarticulated elements. Identification is made, most often by the collaboration of the medical examiner and a forensic odontologist
3	Further destruction of the body is demonstrated by missing major portions of the arms and/or legs. The head is present at this level, although identity is not evident. The search area for associated disarticulated remains should be widened. A forensic anthropologist should be included to facilitate successful search and recovery procedures at the death scene. Identification is coordinated by a medical examiner, who may require the aid of a forensic odontologist. If needed, a forensic anthropologist may be called on to determine sex, age, race, etc., from the skeleton
4	The skull has fragmented and is absent from the body. Some portions of the arms and/or legs may still remain articulated to the charred body. Search and recovery should be aided by a forensic anthropologist, using systematic bioarchaeological methods, including screening procedures to locate small body fragments and dental elements. Identification is coordinated by a medical examiner using a forensic anthropologist and an odontologist as consultants as needed
5	The body has been cremated and little or no tissue is present. The remains are highly fragmentary, scattered, and incomplete. A forensic anthropologist should be an on-site consultant for the identification and recovery of cremains. Personal identification is most difficult at this level, and a forensic anthropologist may be best trained to interpret cremains for identifying physical attributes of the deceased. Recovery of dental elements will require the expertise of a forensic odontologist. As with all fire deaths, a medical examiner is, most likely, the designate to coordinate consultant activities

pose. Meanwhile, depending on the amount of subcutaneous fat, and the presence of clothing, the torso of the body will burn starting with the ribs and the spinous processes of the vertebrae. The body position and location, in relation to other objects, may hinder the burning of the body. This is why the context of the body is of such importance.

The time that it takes to burn a body to CGS 5 is variable. There is a distinct difference between a body burning in a confined space (a house) and an open space (an outdoor fire pit). House fires can easily expose a body to temperatures between 670 °C and 810 °C and after approximately 10 min and may exhibit the "pugilistic pose" (Bohnert et al. 1998). At 20 min, the vault of the skull is free of soft tissue and the outer table may have fissures. At 30 min, the body cavities are visible and a further 10 min of exposure results in shrunken internal organs. At approximately 50 min, the extremities have been rendered to bone and fallen away from the body and may be difficult to discern from the related debris around the body. Beyond this, the remaining torso of the body is further consumed down to calcined bone. The entire process, at the stated temperature range, may take 2–3 h.

Microstructural and Ultrastructural Alterations

Once the soft tissue is eliminated, the exposed bone will also undergo heat-induced alterations. Again, the burning process of bone dehydrates the bone tissue and consumes the organic portion of the bone and even alters the microstructure of the hard matrix. This can result in a color change, splitting, and warping. The color of burned bone may be interpreted in a variety of ways (Fairgrieve 2008: Table 3.5). However, a range of colors exhibited on the same burned bone may be the result of the fuel load, oxygen availability, and contact with other substances, such as metals. The range of color exhibited by burned bone will depend on the temperature reached by the bone, and the duration of time at that temperature. Initially, the bone is a light amber color. The organic components of the bone remain (Fairgrieve 2010). As the process continues, the bone will begin to blacken; the periosteum is burned away and the organic constituents of the bone, including the marrow begin to be consumed. The black color of the bone indicates that the bone has reached a temperature of approximately 300 °C and the lamellar microstructure of the bone persists (for a review see Holden et al. 1995).

A gray color is attained once the bone temperature reaches at least 600 °C. The organic portion of the bone has leached out at this stage. Microscopic spherical-type crystals are formed (Holden et al. 1995). With further exposure to the heat, these crystals change their shape and size. The organizational structure of lamellar bone is broken down. However, bone collagen has been found in bone reaching temperatures of 600 °C (Walker et al. 2008). With further heating, the bone will transition to a blue-gray appearance that may ultimately yield to a final white color. This occurs when the bone has attained a temperature of at least 800 °C. The crystals are now hexagonal, and there is no discernible lamellar pattern (Holden et al. 1995).

Along with these microstructural changes there are associated ultrastructural changes beyond the color changes. With the consumption of the organic portion of bone there is a concomitant reduction in the bone's dimensions (length and caliber). Such changes will affect any metrical analysis of skeletal elements. Therefore, it is generally not recommended to take metrics of burned bones if they are to be used in aging and sexing. However, in order to interpret the presence of any pre-incineration fractures, it is essential that heat-induced fractures be clearly understood.

Heat-induced fractures can be broken down into five general types. *Patina* fractures occur on the surface of a bone. The intersecting surface fractures do not penetrate to the medullary cavity. *Longitudinal* fractures follow the long axis of a long bone and may penetrate the medullary cavity. Such fractures follow the longitudinal orientation of the collagen fibers parallel to the cylindrical osteons. *Curvilinear (or curved transverse)* fractures extend around the bone from one side to the other. *Transverse* fractures are perpendicular to the longitudinal axis of the bone and tend to penetrate through the medullary cavity and may

Burned Remains in Forensic Contexts, Fig. 1 The *arrow* indicates charred residue of material that is the result of venting at the time of burning of a pig (*Sus scrofa*) skull (posterior at *top*). In this case, the presence of venting is evidence of a pre-incineration opening in the skull. The pig was lying on its right side

even divide the bone into proximal and distal portions. *Delamination* fractures appear as a superficial peeling or flaking of bone from a deeper layer of cortical or cancellous bone.

To distinguish the aforementioned heat-induced fractures from peri-mortem trauma, it is necessary to reassemble the pieces and observe the overall fracture pattern. This way heat-induced fractures may be distinguished from tension, compression, and shearing fractures (Mayne 1990). The color of the fracture margins, relative to those that are heat-induced, may assist in the analysis. Additionally, pre-incineration, penetrating trauma, to the cranial vault, will result in the venting and burning of fluid that is forced out of the vault at that location. This discoloration also indicates the orientation of the head during the burning process (see Fig. 1).

Recovery Issues

In forensic contexts, the issues that pertain to burned human remains are similar to those found in archaeological contexts. These issues include the detection, recording, collection, analysis, and interpretation of the remains. Ultimately this process leads to producing a report that meets the needs of investigators and the courts.

The detection of burned remains may be quite simple. Burned human remains may be obvious as a darkened mass within the debris being observed. However, in cases that have remains buried under large amounts of debris, a systematic approach to searching the scene, such as superimposing a grid and proceeding square by square through each level of the debris, will yield the best results.

In certain instances, the use of alternate light sources may be used. Bones and teeth will fluoresce when exposed to light at the violet-blue-green region of the spectrum and viewed through an orange barrier filter (Craig and Vezaro 1998). Calcined bone is not likely to fluoresce with any combination of light and barrier filters, however, burned bones have been found to appear dark purple when exposed to a light of 450 nm (nm = nanometers) when viewed with a yellow barrier filter (Mavin 2001). This may be helpful as the body will burn unevenly and may be at intermediate stages depending on the duration of the burn. Other items in the debris may also fluoresce.

The use of human remains detection (cadaver) dogs is a common practice. Such dogs may be valuable in detecting burned human remains. However, the use of dogs is no substitute for a systematic search as dogs have been known to give false positive indications as to the presence of remains. In all cases, confirmation of positive indications is essential (Fairgrieve 2010).

The documentation of the location and position of burned bone will be more productive if one recalls that the bones of the victim will be found in relative anatomical order unless they have been moved. The position of the remains must be considered in both the vertical and horizontal planes. Remains found in direct contact with the basement floor with debris on top indicate that the victim was in the basement at the time of the burning. Whereas, a victim's remains positioned between debris indicate that their original position was on an upper floor of the house. It is ideal to use computerized survey equipment during the recovery of remains at most scenes. This evidence may refute or corroborate witness and suspect statements.

Burned remains that have been moved out of relative anatomical position may have been subjected to taphonomic forces (Haglund and Sorg 1997). Natural phenomena, such as gravity, can cause the remains to fall through the superstructure of the house, altering their position. However, a perpetrator may have dismembered a body and then burned the remains. Another artificially induced change may come from the recovery process itself. Careful examination of the remains to explain all marks is necessary for a successful analysis.

Analytical Issues

Analytical questions are no different than those of unburned remains. The obvious difficulty is with the fragmentary state of the remains and the friable nature of the bones. This means that the analysis has the potential to be highly limited. However, cataloging all identifiable skeletal elements can yield a minimum number of individuals, as can an overall weight of the remains recovered.

The repair and reconstruction of fragments is done to facilitate the analysis of fracture patterns. The margins of fractures may have been degraded to the point where a physical mend is not possible. However, all mended bones must be photographed both individually and collectively. An overall photograph of the mended bones in relative anatomical order can be a useful visual aid in court. This will also aid in the analysis of fracture patterns and burn patterns.

Age, sex, ancestry, and even stature may be possible to discern from burned remains. However, as fire alters the dimensions of a bone, this must be considered when applying metrics to an analysis (Thompson 2004). As a result, the reliability of analytical methodologies may be called into question.

The analytical goal is to lead to a positive identification of the victim. The remains may be complete enough to use in a comparison of antemortem and postmortem radiographs. DNA may be recovered from burned tissues, in order to arrive at an identity (e.g., Williams et al. 2004). Burned dental remains, such as tooth roots and crowns, may be very helpful in establishing a positive identification (Hardy 2007).

The identification of trauma is a central issue in the analysis of burned skeletal remains. As noted above, the analyst must differentiate heat-induced fractures from traumatic fractures that have occurred antemortem, perimortem, and even postmortem. Fractures without healing are usually classified as perimortem. However, when a non-burned bone is broken after the soft tissue has decomposed, and the bone is dry, there is a color difference between the break and the surface. This can be discerned in burned bone if it is broken after the fire, and the color of the inner bone tissue differs from the exterior. In the case of a bone exhibiting differential burning, the variation of the color of the bone must be considered carefully in order to interpret the nature of the fracture. Generally, fracture margins that are the same color as the adjacent surface usually indicate that the fracture was present at the time of burning. Bones burned to a calcined (white) state tend to be highly fragmented and uniform in color. Hence, determining the relative timing of the fracture may not be possible.

Future Directions

The recognition and analysis of burned human remains in forensic contexts pose various challenges. Knowledge of the uneven burning of a body can assist in the documentation, recovery, and interpretation of the remains. Standard osteobiographical analysis may be limited depending on the state of the burned remains. However, it may be possible to derive the age, sex, and ancestry with such remains. Additionally, a positive identification from the remains, including dental remains, may not be precluded in such cases. The successful outcome of an analysis is dependent upon the documentation and recovery at the scene. Understanding how a body burns is essential to the interpretation of the state of the remains.

Future research directions tend to be in the area defining criteria for the diagnosis of trauma from burned remains. Such new studies include attempts at examining the effects of fire on dental tissues. By defining criteria for the diagnosis of

trauma from burned skeletal remains, the analysis will conform to the standards that are currently being demanded by the courts.

Burra Charter: The Australia ICOMOS Charter for Places of Cultural Significance (1999)

Marilyn Claire Truscott
Donald Horne Institute for Cultural Heritage, University of Canberra, Waramanga, ACT, Australia

Introduction

The Australia ICOMOS *Burra Charter* was first adopted in 1979, in the historic mining town of Burra Burra in South Australia. Since then – with amendments – the Charter has provided guidelines for cultural heritage management in Australia to ICOMOS members, heritage agencies at all levels of government, and planning bodies. ICOMOS, the International Council on Monuments and Sites, is the international non-government professional organization primarily concerned with the philosophy, terminology, methodology, and techniques of conservation for

places of cultural significance. ICOMOS is also an advisor on the UNESCO World Heritage and Intangible Cultural Heritage Conventions and has 100 national committees and 27 specialist committees (see www.icomos.org). Australia ICOMOS is a national committee founded in 1976, now with some 500 members.

The *Burra Charter* reflects an Australian understanding of heritage place conservation practice, and amendments to the Charter over time have incorporated a widened and deepened professional understanding of heritage issues. Widely regarded as best practice, the Charter has been endorsed and accepted by all levels of government in Australia. The *Burra Charter* has also been adopted, adapted, and applied in other countries in all continents. This entry provides an outline of the Charter, its principles and processes, and changes to it over time.

Definition

The Burra Charter: The Australia ICOMOS Charter for Places of Cultural Significance provides guidance for the conservation and management of places of cultural significance. The full text of the Charter is online at http://australia.icomos.org/wp-content/uploads/BURRA_CHARTER.pdf. The *Burra Charter* provides a series of principles and a conservation management process setting a standard for practice for those working in cultural heritage management – primarily heritage places – and related objects, with both tangible and intangible values.

The *Burra Charter* includes definitions, conservation principles and process, and practice (Articles). The Conservation Principles (Articles 2–13) form the basis for the process to be undertaken when making decisions about heritage places as shown in the chart below (Australia ICOMOS 2000: 10). A key principle in the Charter is that the cultural significance of a place is the basis for decisions on managing the place (Article 6.2). Cultural significance is interpreted as having key values for past, present, or future generations (Article 1: 2), namely, *aesthetic*, *historic*, *scientific*, and *social*, with *spiritual* added in 1999. These values are explained further in the guidelines to the Burra Charter: Cultural Significance (Australia ICOMOS 2000: 11–3). The Charter insists that such values may be held by different groups in societies and may conflict, yet should be recognized and respected (Article 13).

A core principle when making decisions about a place assessed as having cultural heritage significance is to take a cautious approach: "changing as much as necessary but as little as possible" (Article 3). Other key principles inherent to the *Burra Charter* are found in Articles 2–13, as summarized by Walker (1996):

- *There are places worth keeping because they enrich our lives – by helping us understand the past; by contributing to the richness of the present environment; and because we expect them to be of value to future generations.*
- *The cultural significance of a place is embodied in its physical material (fabric), its setting and its contents; in its use; in the associated documents; and in its meaning to people through their use and associations with the place.*
- *The cultural significance of a place, and other issues affecting its future, are best understood by a methodical process of collecting and analysing information before making decisions.*
- *Keeping accurate records about decisions and changes to the place helps in its care, management and interpretation.*

The Burra Charter's section on the conservation process (Articles 14–25) refers to more than physical conservation, but the entire range of decisions made including retention of reintroduction of use to reconstruction, adaptation, and interpretation (Article 14). Associations between people and place are to be respected, and opportunities taken for the meanings of place be not only maintained but revived where possible (Article 24). Following the Charter's conservation process in undertaking the relevant research and assessments can better guarantee that decisions about the heritage place are well informed and guided by heritage significance. The following

Burra Charter: The Australia ICOMOS Charter for Places of Cultural Significance (1999), Fig. 1 The conservation process (Australia ICOMOS 2000: 10)

chart demonstrates the *Burra Charter* Conservation Process (Fig. 1):

The *Burra Charter's* section on conservation practice (Articles 26–34) provides some practical guidelines for the hands-on process once cultural significance is established, physical conservation issues identified, and external factors such as planning, zoning, and other statutory considerations. Matters such as dealing with disturbing or removing physical elements and recording all decisions and changes are important when affecting any change to a

heritage place. In doing so, key definitions in the Charter enhance understanding and decisions regarding what actions are appropriate for each individual heritage place, particularly in Article 1:

1.4*Conservation* means all the processes of looking after a place so as to retain its cultural significance.

1.5*Maintenance* means the continuous protective care of the fabric and setting of a place, and is to be distinguished from repair. Repair involves restoration or reconstruction.

1.6*Preservation* means maintaining the fabric of a place in its existing state and retarding deterioration.

1.7*Restoration* means returning the existing fabric of a place to a known earlier state by removing accretions or by reassembling existing components without the introduction of new material.

1.8*Reconstruction* means returning a place to a known earlier state and is distinguished from restoration by the introduction of new material into the fabric.

These definitions clarify the different decisions that can be made and when they are applicable given the potential impacts on the cultural significance on the place, depending on the nature of the heritage values found. Potentially a place where the fabric is of little significance compared to its use and association with the community may be rebuilt as a new structure yet maintain a continued use; whereas another place's significance may reside in its architectural style, therefore to be retained, yet possibly with a quite different use.

Exemplars of best cultural heritage conservation practice have been presented in *The Illustrated Burra Charter*, both in 1992 updated after the 1999 changes to the Charter (Marquis-Kyle and Walker 1992; Walker and Marquis-Kyle 2004). They provide a useful array of situations and issues in heritage management and how such can be resolved by applying the Burra Charter principles and processes. These publications are not available online, but can be purchased from Australia ICOMOS.

Current Debates and Future Directions

Conservation of Places of Cultural Significance, although generally referred to as the "Burra Charter." In 1999 not only were several amendments passed, but a name change was also adopted: *The Burra Charter: The Australia ICOMOS Charter for Places of Cultural Significance*. This is not merely a semantic change but reflects a widened as well as deepened comprehension of heritage places, their values, and associated conservation management issues. While previous amendments in 1982, 1984, and1989 had been relatively minor (these can be found at http://australia.icomos.org/publications/charters/), those adopted in 1999 after five years of member consultation show a greater shift. The name change reflects a move from a focus on purely physical conservation to a broader engagement to sustaining cultural heritage places for all their values, whether expressed in their physical structure or intangibly.

The 1999 amendments resulted in the greatest shifts to its text. The key changes (beyond the change of title) related to the following (see Truscott and Young 2000 for more information):

- A broadening of the understanding of what is cultural significance, not only fabric of a place but its use, associations, and meanings, particularly to relevant community groups (Articles 1.2, 12, 26.3).
- The coexistence of values, particularly perhaps in a multicultural society such as Australia; this also reflects the Australia ICOMOS Code on the Ethics of Co-existence in Conserving Significant Places, adopted in 1998 (Australia ICOMOS 2000: 20–1).
- Reference to interpretation, that the previous Charter had been silent on; it was recognized that interpretation is important and also that restoration and reconstruction are acts of interpretation (Articles 1.17, 25)
- An expanded preamble to make the document more approachable, with a statement about a rationale about "why conserve?"
- Changes to Article 2 to provide an obligation to conserve and a recognition that conservation is an integral part of good management, arguing

that only when conservation is included in other aspects of managing a place will there be satisfactory outcomes.

The review of the Burra Charter that led to the 1999 amendments was in some ways fraught, showing up differences in perceptions of the charter. Some members and heritage practitioners tended to apply the Charter to the letter, in its literal content, others in terms of its intent or spirit. A major conflict occurred in the proposed adoption of the changes in 1997, and the working group went back to a greater consultative process that resulted in an almost unanimous adoption of the amendments at its meeting in 1999 (Truscott and Young 2000).

Australia ICOMOS has a commitment to ongoing review and update to reflect changes in heritage practice. This is unlike the ICOMOS *Venice Charter* (the International Charter for the Conservation and Restoration of Monuments and Sites, see www.international.icomos.org/charters/venice_e.pdf). The Venice Charter has not been changed and in 2004 ICOMOS decided to keep it as an original doctrinal text (see Pécs Declaration: www.icomos.org/venicecharter2004/pecsdeclaration.pdf).

Currently, the Burra Charter is again being reviewed, with proposed amendments expected to be submitted to the membership for comment later in 2013. The guidelines that were not updated in the 1999 amendments are also being updated (Australia ICOMOS 2000: 11–9). Over a decade after the 1999 *Burra Charter* was adopted, the amendments are expected again to reflect changes in perceptions of heritage and practice in its conservation. The amendments will hopefully provide guidance as to how to practice heritage conservation in a way to ensure those changes are incorporated. It is likely that they will include a greater inclusion of community interests and how to balance these with best physical conservation; an appreciation that "experts" and community members have different perceptions of what is important; and a more integrated approach to place, landscape, and the wider environment.

Introduction

The Burrup is a region of Northwest Western Australia known for its petroglyphs, stone arrangements, stone quarries, shell middens, and other archaeological sites (Bird and Hallam 2006). In an area of about 100 km^2, it has been estimated that there are between 0.5 million and 1 million

Burrup Peninsula, Fig. 1 Four Ibis from Gum Tree Valley. (Photo: Iain Davidson)

petroglyphs, some of extraordinary beauty (e.g., Fig. 1), carved on natural blocks of hard granophyre and gabbro. The area is on the Australian National Heritage List (McDonald and Veth 2009), and the case has been made for World Heritage nomination.

Definition

The Burrup is the name given to that part of the Dampier Archipelago which was formerly called Dampier Island. Large concentrations of petroglyphs have been found in many islands of the archipelago. The name change was a consequence of the establishment of several heavy industries in the region (against growing opposition from rock art specialists). The establishment of a salt industry replaced the wetlands that had separated Dampier Island from the mainland and established it as a peninsula – the Burrup.

Key Issues/Current Debates/Future Directions/Examples

History of Industry Impacts on the Cultural Heritage

Aboriginal people generally avoid the peninsula because of the history of massacre in the nineteenth century, but historically, they continued to use it for ceremony, for sheep pastoral activities because of the good water, and as a base for collecting shells. During these activities, elders explained the images to their young people. As a result, present-day Aboriginal people of the Ngarluma (including the Wong-goo-tt-oo, the Coastal Ngarluma), Yindjibarndi, Mardudhunera, and Yaburara recognize the importance of the images which were made by the *Marga* ancestors (Palmer 1975), including ongoing connections to rock art traditions further inland.

Since the 1960s, Western Australian Governments (of all political leanings) have encouraged the development of heavy industry in the region. Before the Western Australian Government (W.A.Govt.) passed the Aboriginal Heritage Act 1974 (AHA) (which offers the possibility of slight protection for heritage), there was a search for a port site in the region for shipping iron ore. This survey suggested that Dampier Island was a better option than Depuch Island, 100 km east of Dampier where petroglyphs had been known since the visit of HMS Beagle in 1840 (Wickham 1842), because a cursory survey had concluded (erroneously) that the petroglyphs on Dampier Island "do not form such a rich display" (Ride et al. 1964). According to anecdotes, when the port was established, there was substantial destruction of petroglyphs without documentation. Further, recent scientific

studies of the threats from industry (Sinclair Knight Merz 2009) to the petroglyphs have shown that there is little threat, but the continuing presence of the port has left the petroglyphs vulnerable to ongoing damage from the presence of particulate iron ore dust in the atmosphere. Chemical concentrations in the atmosphere were all low, lower than those recorded in Karratha, where they are probably due to urban activities rather than the effects of industry.

In the late 1970s, approval was given for a Joint Venture, led by Woodside Energy Limited, to establish a plant for processing liquefied natural gas subject to certain conditions resulting from the application of the AHA. This led to detailed and prolonged field study of the petroglyphs by teams led by Patricia Vinnicombe, Ken Mulvaney and Jim Rhoads (Vinnicombe 2002). Most of this work did not include local Aboriginal participation, although Aboriginal staff from the Western Australian Museum did participate. Many petroglyphs were documented, some were salvaged with the intention of relocating them after the establishment of the gas plant, and others were documented before being destroyed. Those that were salvaged have not yet been relocated (Fig. 2), causing ongoing friction between Aboriginal and other stakeholders in rock art and government and industry. An audit of the petroglyphs on Joint Venture leases in 2007 showed that in many cases where approval had been given for removal or destruction, the petroglyphs are still present in the lease.

In 2003, in advance of a determination on Native Title, the W.A. Govt. established industrial zones on the Burrup and obtained Aboriginal consent through the Burrup and Maitland Industrial Estate Agreement (BMIEA). There is a perception that the W.A. Govt. did not deliver the agreed benefits in return. Approvals under the AHA subsequent to this have followed Aboriginal involvement in surveys, but industries (including another gas plant) have been established against Aboriginal wishes.

Results of Cultural Heritage Work on the Burrup

Attempts have been made, under existing legislation, to mitigate the direct impact of industry in some cases, but government deemed the cumulative impact on sites in the region, and the broader impact on the sites in the landscape less important than the development of industry.

A major conveyor carries salt through the rocky part of southwest Dampier Island (Virili 1977), and Michel Lorblanchet undertook archaeological work (funded by the Australian Institute of Aboriginal Studies, as it then was) in the adjacent Gum Tree Valley and Skew Valley from the early 1970s (Lorblanchet 1992). This work has produced the only secure dates for the production of petroglyphs. These dates come from excavation

Burrup Peninsula, Fig. 2 Outline kangaroo in Salvage Yard. (Photo: Iain Davidson)

Burrup Peninsula, Fig. 3 Turtles from Rosemary Island. (Photo: Iain Davidson)

of shell middens at the entrance of Skew Valley which revealed images produced more than 4,200 years ago. In addition, among the engraved blocks in Gum Tree Valley, Lorblanchet found a trumpet shell which was dated to about 22 thousand years ago. This shell does not definitely date the art but shows that people were present in the region at the period of maximum cold of the last glacial when sea levels were much lower: the shore was 100 km or more distant, and the islands of the archipelago were the tops of hills in the Dampier range. Radiocarbon dates from shell middens on Rosemary Island confirm that the island was used between 9.5 thousand and 7.2 thousand years ago, corresponding to the interval in which the rising sea reached the hill, and then isolated it (Bradshaw 1995). The petroglyphs on the island do not show the full range of images found on the mainland, suggesting that the older ones (including faces called "archaic") predate the earliest shell middens and the latest ones (including many turtles) (Fig. 3) could be later depending on when water crossings became possible.

Burrup Peninsula, Fig. 4 Line of dancing people, Dugong Heights. (Photo: Iain Davidson)

The petroglyphs were made by removing some of the weathered outer surfaces of the blocks, revealing a lighter-colored surface below (Donaldson 2009). Both Lorblanchet and more recently Ken Mulvaney (2013) have documented that there are several stages of weathering after the images were made, allowing the construction of a sequence of relative ages for the images. Some image classes show several stages of weathering. Considering only those that have only one stage, in the oldest class were very small images of birds and quadrupeds and in the next oldest some of the large tracks of birds and macropods as well as large outline images of them. In the second youngest class, there were lines of people dancing (Fig. 4), and, in general, images of fish, turtles (Gunn and Mulvaney 2008), and other marine

Burrup Peninsula, Fig. 5 "Archaic face" at Picnic Creek, showing Joint Venture Plant in background. (Photo: Iain Davidson)

species are the least weathered. Some of the "archaic faces," particularly those with concentric framing (Fig. 5), occurred in the oldest weathering stage (Dix 1977).

Finally, there are many images of the carnivore, *Thylacinus* (Wright 1972), which became extinct on mainland Australia about 3 thousand years ago. These animals were represented at many different times, including some in the oldest weathering stage. They are never in the youngest weathering stage.

Bushell, Robyn

Robyn Bushell
Institute for Cultural and Society and School of Social Science & Psychology, Western Sydney University, Sydney, NSW, Australia

Basic Biographical Information

Robyn Bushell holds a doctorate from the University of Sydney. She is an Associate Professor in the School of Social Science & Psychology and Institute for Culture and Society at the University of Western Sydney. In addition to her interests in cultural heritage research, Professor Bushell has worked for many years with heritage, sustainable tourism planning, and community development across SE Asia in close partnership with UNESCO.

Major Accomplishments

Prof Bushell is an internationally recognized heritage studies scholar. Her research intersects heritage studies, tourism planning, and community wellbeing. She has worked in SE Asia over the past 20 years resulting in over 70 publications: edited books, book chapters, journal articles, commissioned reports, and contributions to international policy documents, including inputs to the CBD Documentation for Sustainable Tourism; UN WTO *Indicators for Sustainable Tourism*; the lead author for the World Health Organization and ASEAN *Healthy Tourism* frameworks; contributor to UNEP *Guidelines on Sustainable Tourism*; UNESCO *World Heritage & Sustainable Tourism Guidelines*, and the revised UNESCO *Hoi An Declaration*. She has worked with international and national natural and cultural heritage agencies for many years including Protected Area Board memberships and reviewing Plans of Management. She has an extensive network of contacts throughout heritage and development agencies involved in work relating to the UN Sustainable Development Goals in SE Asia.

In addition she has contributed to a number of international policy documents – for the IUCN, UNESCO-World Heritage Centre, UN-World Tourism Organization, and the World Health Organization. These include a report to the 34th meeting of the World Heritage Committee as part of the review of the Operational Guidelines for the World Heritage Convention with the development of Principles for World Heritage and Sustainable Tourism practices, which was a joint initiative of UNESCO-World Heritage Committee, IUCN, ICOMOS, and ICROM.

Prof. Bushell initiated and led the European Union – Australian Gov't funded: Post Graduate Training Scheme "*Sharing Our Heritage*": *Master Classes In Cultural & Natural Heritage Management* with in-kind support from UNESCO-WHC and Parks Australia, 2005–2007. The project involved four universities in Australia and four in Europe. She also supervises doctoral scholars engaged in research around a range of topics related to heritage management and community development issues.

Dr. Bushell works with a range of national and international heritage governance bodies and academic institutions. She is a member of Forum-UNESCO; the Australian Department of Environment and Heritage World Heritage Reference Group (2009–2012); IUCN representative on Steering Committee World Heritage and Tourism (2009–2011), Blue Mountains World Heritage Advisory Committee; ICOM-Australian chapter; Ministerial Appointment, Booderee National Park Board of Management, comanaged with the Wreck Bay Indigenous community (2003–2014); Ministerial Appointment to the NSW NPWS Regional Advisory Council for Blue Mountains National Park, Executive Ctee for the Oceania Regional Steering Committee of the World Commission for Protected Areas (WCPA) of the International Union for the Conservation of Nature, IUCN (1998–present); Vice

Chair, International Specialist group on Tourism, WCPA–IUCN (1998–2016); and IUCN "Healthy People Healthy Parks" Steering Committee (2011–). She was a member of the Expert Liaison Committee for Protected Areas to develop input to the SBSTTA 9 for the Convention on Biological Diversity (1998) and member of the UN-World Tourism Organization Expert Advisory Group on Indicators of Sustainable Tourism.

Butzer, Karl W.

Rolfe D. Mandel
Kansas Geological Survey and Department of Anthropology, University of Kansas, Lawrence, KS, USA

Basic Biographical Information

Karl W. Butzer (1934–) is an American geographer, geoarchaeologist, cultural ecologist, and environmental archaeologist. Much of his research has focused on the relationships between the environment and prehistoric people and more recent societies. He has collaborated with many paleoanthropologists and archaeologists, working at both larger, regional scales and at the site-specific microlevel.

He was born in Germany and emigrated to England and then Canada as a child. He attended McGill University, where he received a B.Sc. in Mathematics (1954) and an M.Sc. in Meteorology and Geography (1955). With the support of an Exchange Fellowship, he went on to the University of Bonn (Germany), where he received a Doctor of Science (Dr. rer. nat.) in Physical Geography and Ancient History (1957).

After 2 years as a research associate at the German Academy of Sciences and Literature, he was appointed Assistant and then Associate Professor at the University of Wisconsin-Madison (1959–1966). In 1966 he took a position as Professor of Anthropology and Geography at the University of Chicago and in 1980 was named the Henry Schultz Professor of Environmental Archaeology. During 1981–1982, he was Chair Professor of Human Geography at the ETH (Swiss Federal Institute of Technology), Zurich, but returned to Chicago. During his tenure at Chicago, he was elected to various sub-departmental units, including the Committee on African Studies, Committee on Evolutionary Biology, and Committee on Archaeological Studies (Humanities). He also served as Professor in the Oriental Institute.

In 1984 he joined the faculty of the Department of Geography and the Environment at the University of Texas, Austin, where he is today, and was named the Raymond Dickson Centennial Professor of Liberal Arts. In 1995 he was Cecil and Ida Green Visiting Professor at the University of British Columbia.

Major Accomplishments

During the early part of his career, his research focused on two general topics: the geomorphology, geoarchaeology, and Quaternary climates of Egypt (especially Nubia) and the paleoecology and geochronology of early hominins. His dissertation, *Quaternary Stratigraphy and Climate in the Near East*, was largely based on his field research in Egypt and was published in 1958 and

reprinted in 1969. As a member of the Yale Prehistoric Nubia Expedition of 1962–1963, he spent seven months in the field studying late Quaternary landscape evolution and the prehistoric archaeological record in Egypt's southern Nile Valley. His early research on Egypt was coalesced in two major works: *Desert and River in Nubia*: *Geomorphology and Prehistoric Environments at the Aswan Dam* (1968) and *Early Hydraulic Civilization in Egypt*: *A Study in Cultural Ecology* (1976). The latter was the first effective attempt to isolate, understand, and synthesize the critical factors involved in the rise of an "irrigation civilization."

In the late 1960s and early 1970s, he turned his attention to the paleoecology and geochronology of early hominins. He participated in the University of Chicago Omo Expedition in southwestern Ethiopia (1967–1969), which involved collaboration with Richard Leakey, and in 1971 and 1973 he worked independently at Axum, Ethiopia. He was especially interested in the paleoecology of the African australopithecines and *Homo erectus*, Neanderthal spatial behavior, and the first appearance of anatomically modern humans. His argument that both archaic and modern *Homo sapiens* coexisted 135,000–65,000 years ago is supported by the results of recent biomolecular research.

The early part of his career also included research in Spain and South Africa. He was involved with the University of Chicago's excavation of Acheulian sites at Torralba and Ambrona in central Spain (1961–1963, 1967, 1980–1981), and he directed the Sierra de Espadan Project in anthropology, historical archaeology, and environmental history (1980–1987). Also, he conducted independent research in Mallorca and Catalonia, Spain (1969–1971). Between 1969 and 1983, he spent 9 field seasons investigating the geoarchaeology of some 30 sites, including Taung and Swartkrans, in South Africa.

During the second half of his career, he focused on the more recent prehistoric and historic periods in order to obtain and interpret high-resolution records, including written accounts, of human impacts on the environment. The skills of his wife, Elisabeth Butzer, in archival research and interviewing have been key factors in facilitating this change of direction. For example, as director of the University of Texas Laguna Project (1995–2000), he considered the recent environmental history of northern Mexico. This project led to a series of papers with Elisabeth, all heavily based on archival sources, addressing the impact of livestock grazing on Colonial Mexico. In a similar study, he evaluated the environmental impact of livestock introduction to New South Wales, Australia (with David Helgren, 1999, 2003). He also has investigated the recent history of French coastal reclamation in Nova Scotia (1999), the environmental history and geoarchaeology of Cyprus (2004), and the geoarchaeology of Celtic hillforts in northern Portugal (2010–2011).

He is author or editor of 15 books and monographs and author or coauthor of some 275 refereed, scientific papers or book chapters. His seminal book, *Environment and Archeology*: *An Introduction to Pleistocene Geography*, was first published in 1964; a new and expanded edition, with the subtitle *An Ecological Approach to Prehistory*, appeared in 1971. This work served to shift "environmental archaeology" from a technical to a synthetic and processual overview of world prehistory. He characterized Pleistocene geography as "environmental reconstruction as applied to an understanding of ecological setting and prehistory" and took issue with Gordon Willey and Philip Phillips' (1958) acclamation that "archaeology is anthropology or it is nothing," pointing out that "Archaeology. . .has been equally dependent on geology, biology, and geography. . .during its development [and] is heavily dependent on the natural sciences."

His book *Archaeology as Human Ecology* (1982) represents another major contribution to the archaeological community. In that work he stressed the significance of "contextual archaeology," whereby archaeological sites are placed in their cultural, biological, climatic, and landscape context. This approach is now standard in archaeological investigations.

He has received many awards and honors in recognition of his contributions to archaeology, geoarchaeology, and geography, including a Guggenheim Fellowship (1976), the Royal Geographical Society's Busk Medal (1979), the Society for American Archaeology's Fryxell Award for Interdisciplinary Research (1981), the Geologists' Association of London's Henry Stopes Medal (1982), the Geological Society of America's Rip Rapp Archaeological Geology Award (1985), and the Archaeological Institute of America's Pomerance Medal (1991). He was elected a Fellow of the American Academy of Arts and Sciences in 1984 and a Fellow of the National Academy of Sciences in 1996.

During the course of his career, Karl Butzer has been at the forefront of geoarchaeology, cultural ecology, and environmental archaeology. He is often described as one of the "fathers" of geoarchaeology, and he remains deeply engaged with interdisciplinary environmental archaeology and history.

C

Cahokia

Julie Zimmermann Holt
Department of Anthropology, Southern Illinois University Edwardsville, Edwardsville, IL, USA

Introduction

Cahokia is the largest and most complex archaeological site north of Mexico; indeed, it was probably one of the largest cities in the world at its peak around CE 1200 (Fig. 1). Because of its "outstanding universal value," it is recognized by UNESCO as a World Heritage Site. To the local community, Cahokia is known as "Cahokia Mounds" because of the many mounds located there. To the archaeological community, however, there is a much greater story hidden below the modern ground surface. While archaeologists have studied Cahokia for much of the past century, it was only with interstate highway construction beginning in the 1970s that serious attention was paid to the smaller sites that supported Cahokia. They too tell an important part of Cahokia's story. The "downtown" portion of Cahokia can be visited at Cahokia Mounds State Historic Site in Collinsville, Illinois.

Definition

Lying across the Mississippi River from modern day St. Louis, Cahokia in its heyday served as a cosmopolitan gateway (Kelly 1991) just as historic St. Louis did. As many as 20,000 people may have lived at Cahokia, but most visible to the casual visitor today are the mounds they built. At least 120 mounds have been recorded at Cahokia, the largest of which, Monks Mound (Fig. 2), is approximately 100 ft tall and has a footprint of approximately 17 acres (Fowler 1997; Dalan et al. 2003). Other monumental features of the site include a palisade and so-called woodhenges.

Key Issues/Current Debates/Future Directions/Examples

Cahokia is situated in the heart of the American Bottom, a vast and rich expanse of Mississippi River floodplain (Iseminger 2010). Mobile hunter-gatherers "camped" at Cahokia as early as the Late Archaic period (3500–1000 BCE), gathering nuts, hunting deer and other native fauna, and fishing in nearby Cahokia Creek and backwater lakes. However, even at this early date, inhabitants of the American Bottom probably experimented by growing native plants such as squash (*Cucurbita pepo*) and goosefoot (*Chenopodium berlandieri*). Cahokia was again occupied during the Late Woodland Patrick phase (CE 700–900). At this time, Cahokia was probably just one of a number of small horticultural villages dotting the American Bottom. Their inhabitants grew squash, goosefoot, and a host of

Cahokia, Fig. 2 Monks Mound, Cahokia. (Courtesy of Cahokia Mounds State Historic Site)

other native plants in their gardens. A newly introduced technology, the bow and arrow, would have improved the efficiency of hunting. After CE 900, maize was brought to the American Bottom and quickly became a staple, yet Cahokians and their neighbors continued to rely on native cultigens, nuts, and wild game. As the population of the American Bottom grew, fish, a resource more easily renewed than deer, was increasingly important in the diet. Despite the diversity of the subsistence base, however, there can be little doubt that the growth of Cahokia in the Mississippian period (CE 1050–1400) was fueled by maize agriculture.

Around CE 1050, Cahokia experienced its so-called "Big Bang" (Pauketat 2004, 2009), and it was no longer just another American Bottom farming village: most archaeologists would agree it became a city unlike any other north of Mexico. Whether Cahokia's seemingly meteoric rise was led by a single charismatic individual or a powerful family is unknown. However, it seems likely that Cahokian society, like any Native American society, would have been focused on kin networks, and kin support would have been necessary for the reorganization of society. The exact nature of Cahokia's new power structure is also debated. The dominant model since the highway archaeology of the 1970s, with its focus on rural sites, has been that Cahokia was the center of a chiefdom (Milner 1998). Despite the acceptance of this model, it is commonly acknowledged that by virtually any measure, Cahokia was something monumentally greater than any other Mississippian chiefdom. For example, although Moundville, Alabama, is often claimed to be the second largest Mississippian center, it had only around 25 mounds, and all of Moundville would have fit within the Grand Plaza of Cahokia (Dalan et al. 2003). By mound count alone, the second largest Mississippian site was actually the East St. Louis site, with approximately 50 mounds; St. Louis, known historically as "Mound City," featured another 25 mounds or so. If not for the Mississippi River and other water features, Cahokia and the sites at East St. Louis and St. Louis would likely have merged to form continuous suburban sprawl. Clearly, though, the center of power was at Monks Mound. The idea that Cahokia was the center of the "Ramey State" (O'Brien 1991) has recently been reevaluated, but rejecting a western notion in which the power of the state is based on coercive power (Holt 2009). Instead, Geertz's "theatre state" model (Geertz 1980) seems more appropriate: that is, Cahokia's power was based on theatrical rituals which drew people to Cahokia. People helped build Cahokia, helped feed Cahokia, and sometimes gave their lives for Cahokia, not because they were forced but because they wanted to take part in this dramatic and monumental social experiment.

Rural villages and isolated farmsteads in the American Bottom and adjacent uplands probably grew surpluses of maize to send to Cahokia (Lopinot 1997). They probably also gave tributes of venison to be served at Cahokian feasts (Kelly 2001). Like the residents of Cahokia, these rural farmers lived in small, single-family thatch houses, but they had access to fewer exotic goods than Cahokians did (Pauketat 2004). Still, given that they were part of the Cahokian social and ritual arena, those rural farmers were probably considered Cahokians. Their labor would have been necessary to build not only Cahokia's many mounds but also its multiple plazas, massive palisade, and woodhenges. The woodhenges, for example, were built at Cahokia's peak, west of Monks Mound. These monumental circles of large posts are believed to have served as sun calendars, but they might also have played a role in mourning and warfare rituals. The Grand Plaza in downtown Cahokia covered an area two or three times the foot print of Monks Mound, and leveling this area would have required as much effort as building Monks Mound (Dalan et al. 2003). Around CE 1200, a massive palisade was built to surround Monks Mound, the Grand Plaza, and other mounds at the heart of Cahokia. What residents might have been protecting themselves from is unclear. It seems unlikely that there was a group large or organized enough to offer serious threat to downtown Cahokia, although evidence of burning at the East St. Louis site might indicate competition from within the American Bottom.

Perhaps the strongest indicator of conflict or coercive power found at Cahokia is the evidence

of human sacrifice at Mound 72 (Fowler et al. 1999). The primary burial in this mound contained a middle-aged man laid upon a bed of marine shell beads in the shape of a hawk; a second man was buried face down beneath him, and abundant grave goods, many exotic, were buried nearby. Some 250 other people were also buried in Mound 72. These were buried in groups of up to 50 people, mostly young women. Another notable burial in the mound contained four headless, handless young men. Fowler, who excavated the mound, argued that the sacrificed individuals were retainers buried to accompany the high status man in the main burial. However, Hall (2006) suggests these were ritualized or "scheduled deaths," not simply retainer burials. Similarly, Brown (2003) suggests these deaths were part of a theatrical reenactment of the Red Horn myth. Thus, these deaths were likely part of a dramatic ritual, and participation was probably an honor. Evidence of mass human sacrifice at Cahokia therefore need not be interpreted as evidence of conflict or coercive power.

Given that it was the earliest and greatest Mississippian center, Cahokia's influence on contemporary and later societies might be seen through the spread of the so-called "Southeastern Ceremonial Complex" (Brown and Kelly 2000; Brown 2004). While Cahokians did not invent mound building nor did they necessarily invent the mythology and associated symbols that they surely exported, their city served as a model for others to imitate. Cahokians surely made ties with contemporary peoples through reciprocal exchanges of material goods and, in common Native American fashion, through adoption ceremonies and creation of fictive kinship ties (Hall 2006). Material evidence of these exchanges would include the presence at Cahokia of marine shell from the Gulf Coast and copper from the Great Lakes. Artifacts probably manufactured at and exported from Cahokia would include Ramey incised pottery found at sites such as Aztalan (in modern day Wisconsin) and flint clay sculptures found at sites including Spiro (in modern day Oklahoma). Given the clear material links between Cahokia and sites such as Aztalan and Spiro, these distant groups may also have seen themselves as Cahokian kin, at least adopted kin. Indeed, sites to the north such as Aztalan and Dickson Mounds (in Illinois) have been interpreted as colonies of Cahokia (O'Brien 1991). While the ceramic diversity at Cahokia and in the greater American Bottom can be seen as evidence that theirs was a multiethnic society, at the same time Native American notions of adoption and kinship suggest that Cahokians and at the very least other residents of the American Bottom saw themselves as a single people.

Although the hypothesized Big Bang that began Cahokia's ascendancy may be metaphorical, the city might have ended with a more literal bang. A multitude of environmental factors, some beyond human control and others directly caused by humans, probably reduced the desirability of Cahokian real estate over time. Cahokia seems to have reached its peak during a period of favorable climate; bountiful maize harvests during this time probably increased the carrying capacity of the American Bottom significantly and enabled Cahokia's rise. Later, a period of recurring drought (Benson et al. 2009), possibly associated with the cooling of the Little Ice Age, may have contributed to Cahokia's demise. Agricultural yields would have been diminished not only by drought but also by decreasing soil fertility caused by growing maize (which is nitrogen-depleting) without beans (which are nitrogen-fixing). Despite the episodes of drought, flooding of farm fields, not to mention homes, would have become an increasing problem, due to deforestation (Lopinot and Woods 1993). Deforestation would have occurred when clearing agricultural fields and also to provide wood for fuel and construction of houses, woodhenges, and the palisade, which was rebuilt several times. Deer herds were probably diminished, which meant not only a decrease of meat in the diet but also a loss of deer bones and antler for tools, and hides for clothing and coverings. The quality of the diet would have also been reduced by heavy reliance on maize without beans to balance protein content. The ultimate bang, however, might have come with an earthquake emanating from the New Madrid fault (Pauketat 2004; Holt 2009). The New Madrid earthquakes of 1811–12 devastated agricultural systems, flattened forests, and even reversed the course of the Mississippi River.

A bang such as this might have been the final straw for Cahokian society, which was already struggling with mounting environmental and presumably social challenges.

At Cahokia we can see the transition from a mobile hunting-gathering society, experimenting with horticulture, to a complex, sedentary agricultural society. It might be tempting to say that the experiment failed, or at least that the environment failed, in the end. However, it is important to stress that Cahokians did not simply disappear. While the Mississippian groups of the southeast encountered by the Spanish might be thought of as their cultural descendents, many archaeologists today think that Siouan groups such as the Omaha, Osage, and Ponca were the actual descendents of the Cahokians (Hall 2006). That is, Cahokians did not die out: they adapted to the dynamic world they lived in, moving on to make new lives elsewhere.

Çambel, Halet

Ece Birçek
Istanbul, Turkey

Basic Biographical Information

Halet Çambel was born in Berlin in 1916 where her father was a military attaché. She graduated from Arnavutköy American College for Girls in 1935, and went to Paris to study at the University of Sorbonne education in archaeology, Hittite, and ancient Hebrew. She completed her M.A. in 1938, and wanted to return to the university to start research for her Ph.D. dissertation, but World War II had just begun. Halet Çambel was the first Turkish woman to participate in the Olympic Games, competing in fencing with Suat Fetgeri Aşeni in 1936.

Major Accomplishments

Çambel attended excavations held by the French Archaeological Institute in Afyon Yazılıkaya/Midas City in 1939, and later, she continued to work with the excavation director, Dr. Emilie Haspels, in the archaeological museums of Istanbul. Later Prof. Dr. Bossert, from Istanbul University, invited her to be his assistant in 1943. She carried out a controlled excavation in Kırşehir Hashöyük on behalf of the Turkish Historical Society. With Prof. Dr. Bossert, she participated in numerous research trips all around Anatolia until 1946 when the site of Karatepe, which created a strong impact on Anatolian archaeology, was discovered.

While continuing to work in Karatepe, she carried out the excavations of Afyon Yazılıkaya/Midas City with the French Institute of Archaeology in 1948and 1949, and Istanbul Fikirtepe with Kurt Bittel in 1950 and 1951. As well as starting site restoration after 1952, she helped to organize Karatepe-Arslantaş National Park, the first open-air museum in Turkey.

Çambel became professor in 1960, and was a guest lecturer at the University of Saarbrücken in 1962 and 1963. When she returned to Istanbul University, she founded the Department of Prehistory at this university. Between 1965 and 1966, she documented archaeological values in Adana region for a study organized by the Bank of Provinces.

Çambel organized a comprehensive study of antiquities around Adana, Hatay, and İçel with a student team during 1966–1971 with the cooperation of State Planning Organization and the Çukurova Regional Directorate of Ministry of Development Planning Project.

In association with the Prehistoric Southeastern Anatolia Research Project, Çambel made a large scale survey in Siirt, Diyarbakır, and Şanlıurfa provinces which afterward led to excavations in Urfa Biris Cemetery and in Diyarbakir Girikihacıyan.

Her other significant study was the excavation of Çayönü which started in 1964.

She organized a team from İstanbul and Michigan Universities to screen the region which was going to be inundated after Keban Dam construction in 1966. This study led to projects by Middle East Technical University for Keban recovery and evaluation of historic monuments (1967) and Lower Euphrates (1974). She also accomplished salvage excavations in Kumkale and Domuztepe from 1981 to 1984.

Even after her retirement in 1984, she continued to carry out the studies in Karatepe and Çayönü as well as the development of projects in Karatepe open-air museum, and at the national park. Halet Çambel received numerous awards including the Kingdom of the Netherlands, Prince Claus Award (2005), awards from Republic of Turkey Ministry of Culture, Troy Culture and Arts, and the University of Tübingen (Germany) honorary doctorate (2004). She is the member of many scientific institutions such as The German Archaeological Institute, the American Philosophical Society for the Advancement of Knowledge, and the American Institute of Archaeology, Thracology Institute.

Cambodia: Cultural Heritage Management

Dougald J. W. O'Reilly
Archaeology and Anthropology, Australian National University, Canberra, ACT, Australia

Introduction

Cambodia, in terms of cultural heritage, is one of the world's wealthiest countries, but the kingdom's economic poverty places this marvelous heritage in constant peril. Since the cessation of hostilities in the late 1990s, much effort has been expended in protecting Cambodian heritage sites with governmental agencies including the Ministry of Culture and Fine Arts, the APSARA Authority, and intergovernmental organizations such as UNESCO working to safeguard sites around the country. More recently, non-governmental organizations, such as Heritage Watch, have been founded to highlight the threat to prehistoric heritage in Cambodia. This entry briefly examines the efforts of these varied organizations and the changing threats to Cambodia's heritage.

Key Issues/Current Debates/Future Directions/Examples

Cambodia is home to a rich cultural heritage which stretches into the prehistoric period. The first Khmer polities, however, were established in the fourth to fifth centuries CE, with the rise of polities known as Funan and Chenla which grew powerful due to the burgeoning trade between the Indian subcontinent and China.

Over time, power became concentrated in Cambodia's North, culminating with the civilization of Angkor which reached its zenith in the twelfth to thirteenth centuries CE, which held hegemony over much of Southeast Asia. The Angkorian empire has left its mark on the region in the form of temples, reservoirs, and roadways, most concentrated within modern Cambodia.

Cambodia's heritage has been treasured and coveted for hundreds of years. Thai invaders carried off innumerable treasures (and many of the skills of the Royal court) in the fifteenth century, some of which now rest in Myanmar after the Thai themselves were invaded by the Burmese. Further depredations against Cambodia were seen under the French protectorate. The tale of André Malraux's attempts to pillage the magnificent temple of Banteay Srei is well known. The French, while they did carry off a good deal of the kingdom's treasures for Parisian museums, did make efforts to conserve much of Cambodia's heritage through the enactment of legislation. These laws, in fact, were cited in the arrest of Malraux.

There have been significant developments both positive and negative in the field of heritage management in Cambodia since the country's independence in 1953. The civil war in Cambodia represents the lowest ebb for Cambodia's heritage as countless statues and other treasures were spirited out of the country.

As Angkor continues to attract thousands of tourists, the pressure on Cambodia's heritage is of a different nature, one in which the masses of tourists are managed while the site retains its integrity. The international community has become involved in Cambodia in the form of the United Nations Educational, Scientific and Cultural Organization (UNESCO). The organization was established in Cambodia in the 1950s but closed in 1975 due to the conflict. In May 1989, UNESCO was able to complete an initial assessment of the safeguarding needs of Angkor, and an office was reestablished in 1991.

UNESCO has several goals in Cambodia:

1. Design and implement programs and projects contributing to strategic objective of UNESCO in the country.
2. Develop projects, raise funds, and implement the projects in the areas of the competence of the Office to reinforce program activities.
3. Promote and enhance partnerships and networks for disseminating and sharing information and ideas with the stakeholders in the country.
4. Enhance the capacity of the staff for strategic planning and management of the programs and projects for delivering results in the country.
5. Position the environment of the Office for efficient and effective delivery of programs and projects in the country.
6. Prospect and expand knowledge management of the Office to facilitate decision making and problem solving by the staff for the delivery of results (REF 2008 UNESCO Phnom Penh Office Annual report).

UNESCO's budgetary expenditures are indicative of the importance the organization places on culture. Twenty-five percent of the budget (in 2009–2010) is dedicated to culture vs. other priority areas (education, natural sciences, communication and information, and program support costs) (UNESCO 2010: 16). Further, many of the extra-budgetary expenses are focused on culture (87% in 2009–2010), mostly the conservation and restoration of temples around the country.

In 1993 the site of Angkor, comprising hundreds of monuments, was inscribed to the World Heritage List and the International Coordinating Committee for the Safeguarding and the Development of the Historic Site of Angkor (ICC-Angkor) was established, under the patronage of the Japanese and French governments. Annual meetings hosted in Siem Reap by the APSARA National Authority in charge of the management of the site, UNESCO, and the international community ensure proper management of the site. Independent experts in conservation, archaeology, and sustainable development oversee project quality and project management. In 2008 UNESCO's Phnom Penh Office in close cooperation with the World Heritage Centre negotiated a "Heritage Management Framework" project with the Australian Government and Cambodian authorities. The project is designed to strengthen the technical expertise and governance of APSARA, so that the benefits of tourism and development at Angkor can be shared fairly, as well as to ensure environmental protection.

The temple of Preah Vihear, situated in Cambodia's north, on the edge of the Dang Rek Mountain Range in Preah Vihear Province, was inscribed as a World Heritage site in 2008. The Cambodian government has established the National Authority for Preah Vihear (NAPV) to function much in the same way as the APSARA Authority does. The challenges to protecting the temple have, so far, been substantial as the nomination to World Heritage status has contributed to an escalation in armed conflict between Cambodia and Thailand. Thailand objected to the nomination and has never fully accepted the International Court of Justice's 1962 decision that found "that the Temple of Preah Vihear is situated in territory under the sovereignty of Cambodia." Internal political maneuvering within Thailand since 2009 has seen an escalation in tension at the site and conflict resulting in several civilian and

military deaths (National World Heritage Committee 2009).

Intangible Cambodian heritage has also been inscribed on the World Heritage List, including the Royal Ballet of Cambodia or Khmer Classical Dance. UNESCO proclaimed Khmer Classical Dance as a Masterpiece of Oral and Intangible Heritage in 2003 and inscribed it on the Representative List of the Intangible Cultural Heritage of Humanity in 2008. *Sbek Thom*, a form of shadow puppetry, was also recognized as a Masterpiece of the Oral and Intangible Heritage of Humanity in 2005, and in 2008 it was also inscribed on the Representative List of the Intangible Cultural Heritage of Humanity (National World Heritage Committee 2009).

In an effort to further support intangible heritage and the knowledge that is passed through the generations, the Spanish government supported the Creative Industries Support Programme (CISP). The project was designed not only to promote the preservation of heritage but also to provide sustainable income for the poor in remote parts of Cambodia, with a strong focus on Cambodian indigenous peoples. The project, which involved four UN agencies, aimed to select traditional crafts, art, and performances and promote them as commercially viable ventures. Efforts were also made to "improve the capacity of national institutions to preserve and develop Cambodia's cultural heritage and living arts, to improve employment opportunities and income generation in the creative industries, to improve the commercialisation of local cultural products and services, and to empower women and indigenous peoples" (UNESCO 2011).

Aside from UNESCO and multinational organizations, there have been other initiatives that have sought to promote heritage preservation in Cambodia. The NGO Heritage Watch was established in 2003 following the rise in looting of prehistoric sites in Cambodia. The illegal excavation and sale of prehistoric artefacts is, perhaps, the largest challenge facing Cambodia's heritage professionals. Where previously temples were targeted, now it is archaeological sites, usually cemeteries containing burials with semiprecious stones, metal, and ceramic artefacts, that are being destroyed.

With funding from the US Department of State, it launched a national public awareness campaign targeting both those who loot and those who buy antiquities. Heritage Watch attacked the supply end of the trade through radio and television commercials, educational comic books, and community workshops for villagers in heavily looted areas and the establishment of a telephone hotline. Tourists were informed about the negative consequences of buying looted antiquities through public exhibits, airport kiosks, and public lectures.

Early in 2006, Heritage Watch began rescue excavations at Wat Jas, an Iron Age cemetery in northwestern Cambodia that was increasingly targeted by looters. This project also involved the training of young Cambodian archaeologists in survey and excavation techniques. In addition to this, Heritage Watch documented threatened sites across the country, recording at-risk objects in case they are stolen in the future.

At the ancient temple complex of Koh Ker, Heritage Watch launched an innovative project combining preservation with sustainable tourism development. Small business training, language skills, craft production, and tourism activities were introduced at Koh Ker to provide the locals with an alternative to looting. Also, Heritage Watch furthered its educational efforts with the publication of a children's storybook promoting heritage preservation that was distributed for free in many Cambodian schools.

2007 saw the launch of the Heritage Friendly Tourism campaign in Cambodia. The aim of the campaign is to encourage responsible tourism, raise interest in remote heritage sites (improving their chances of protection), and encourage corporate Cambodia to support art, heritage, and development. The campaign involved a major advertising push encouraging visitors to Cambodia to support businesses that have been certified as Heritage Friendly (in that they actively supported the aforementioned sectors).

Other initiatives include the Database of Historical and Archaeological Regulations for the Management of Antiquities (DHARMA), the aim of which is to compile a resource of all laws that are applicable to Cambodian heritage issues

in one location. Heritage Watch has also been involved with the training of guides at the temple site of Banteay Chhmar in Cambodia's Northwest as part of an effort to boost tourism to the local community and reduce heritage destruction in the area, one of Cambodia's worst affected by looting. In 2011, Heritage Watch worked with the Australian government in the repatriation of antiquities smuggled into Australia and also assisted in establishing a bilateral agreement between the Australian and Cambodian government that will limit the illegal trade in antiquities.

The Phnom Kulen Archaeology and Sustainable Development Program is a project of the Archaeology and Development Foundation (ADF), a London-based nongovernmental organization. In this innovative program, archaeology and sustainable development go hand in hand. Working to the north of Siem Reap, this site-specific effort has four main components which aim to reduce poverty and strengthen civil society. The emphasis is on letting the local community at Kulen make their own decisions regarding food security, health center support, infrastructure and education, and income generation. This program provides an excellent model in the ways archaeological research, heritage preservation, sustainable development, and tourism can work together successfully.

The Ministry of Culture and Fine Arts (MoCFA) of Cambodia also has taken great steps in efforts to protect Cambodia's cultural heritage. Two bilateral agreements have been signed by the MoCFA with the United States that limits the export of antiquities from Cambodia. As the government ministry charged with protecting Cambodia's heritage, the MoCFA is an integral part of all efforts in heritage preservation and works closely with NGOs and UNESCO in these efforts.

Cambodia faces considerable challenges in protecting the vast heritage resources it is blessed with, ranging from the monuments of the Angkorian period to the subsurface remains of prehistoric sites and cemeteries, as well as its living heritage, that is under continual threat. There is, however, considerable support for Cambodian heritage, and it is a question of whether this support will balance the demand for Cambodia's antiquities. Past trends suggest not and the difficulty nongovernmental agencies working in heritage face in raising funds further suggests that the challenge to protect Cambodia's treasures will be an uphill battle.

Camels: Domestication

Alexandra Trinks
Archaeology Department, Durham University, Durham, UK

Basic Species Information

Systematic Classification

- *Camelus ferus* wild two-humped camel
- *Camelus bactrianus* domesticated two-humped/Bactrian camel
- *Camelus dromedarius* domesticated one-humped/Arabian camel/dromedary

The genus *Camelus* contains the domestic species *Camelus bactrianus* and *Camelus dromedarius* (Walker 1964). In 1877 N. M. Przewalski discovered the wild two-humped camel (*Camelus ferus*) while on expedition in Eurasia (Przewalski 1879; Bannikov 1976; Hare 1997). Archeologists commonly assume the extant wild two-humped camel *C. ferus* to be the progenitor of the domestic two-humped camel *C. bactrianus* (Benecke 1994; Peters and von den Driesch 1997); however, recent paleogenetic studies show that *C. bactrianus* more likely originated from an as yet undetected wild camel species (Trinks et al. 2012).

Phylogeography of Old World Camels

The family *Camelidae* originated during the Eocene, about 40–45 Ma ago in North America (Gauthier-Pilters and Dagg 1981). Four to five million years ago, the ancestors of the modern New World camels dispersed from the North into the mountainous regions of South America, while *Paracamelus*, the progenitor of modern Old World camels, reached Eurasia about three million years ago via the Bering landbridge (Gauthier-Pilters and Dagg 1981; Koehler 1981; Peters 1997). The remaining camel forms in North America disappeared ~10,000 years ago due to climatic changes (Irwin-Williams 1967; Frison et al. 1978).

The earliest camel forms were well adapted to the open steppes and spread rapidly westward after migrating to Eurasia. By the middle Pleistocene, the habitat of the Old World camels ranged from Central Asia to the Arabian Peninsula, including parts of North Africa and Eastern Europe (Koehler 1981; Titov 2008). Fossil evidence has yet to substantiate whether the different number of humps is related to adaptation to diverse environments. Paleolithic cave paintings (Chojt-Zenker cave) in Eastern Mongolia suggest that the existence of a wild two-humped camel is certain at least for Central Asia (Nowgorodowa 1980; Benecke 1994).

By the end of the Pleistocene, a severe reduction in the range of wild camels occurred as a result of change towards a dryer climate (with the beginning of the Dnepr-Ice Age) and increased human hunting activities (Gauthier-Pilters and Dagg 1981; Kozhamkulova 1986; Titov 2008).

Over time, the wild camel species inhabiting the steppes and semidesert of the Old World became extinct, leaving only *C. ferus*. Today, the distribution of the remaining 900–1400 individuals is restricted to parts of the Chinese and Mongolian Gobi desert (Bannikov 1976; Hare 1997; Mix et al. 1997, 2002; Reading et al. 1999).

C. bactrianus, the domestic form, has spread throughout the dry steppes and semidesert zones in Central Asia and is now found from Northeast China, Mongolia and Siberia, in Kazakhstan, South Russia, and parts of Afghanistan, Pakistan, and Iran. In Asia Minor, its distribution overlaps with that of the one-humped camel *C. dromedarius* (Walker 1964).

Archaeology and Domestication of the Two-Humped Camel

The domestication of the two-humped camel, used as a pack, draft, or riding animal, but also for milk, meat, and wool production, built the basis for long-distance trade between the Central Asian steppes and Europe during the Bronze Age (Benecke 1994; Kuzmina 2008). Archeological evidence suggests that camel husbandry gained importance during the second millennium BCE, though where the domestication process began remains controversial.

Archeological records show evidence for a closer relationship between people and the two-humped camel during the late fourth and beginning third millennium BCE (Bulliet 1975; Benecke 1994). The earliest records of camel bones come from sites of the Kopet-Dagh foothills in the borderland between Turkmenistan and Iran dating to the second half of the fourth millennium (Kuzmina 2008). A similar situation appears at the northern edge of Kopet-Dagh mountains, where archeological layers at Shor- and Khapuz Depe produce finds of *C. bactrianus* dating to the early third millennium BCE (Compagnoni and Tosi 1978). Further, camel bones dating between 2500 and 2200 BCE originate at Turkmen settlements of Altyn Depe, Namazga Depe, and Kelleli (Peters and von den Driesch 1997; Kuzmina 2008). At the site of Shahr-i-Sokhta (Iran), camel bones and finds of hair and collected camel dung (which replaces the scarce firewood in the usually

treeless steppes) dating to the first half of the third millennium suggest the presence of animals that lived in close association with the site inhabitants and hence represent domesticates (Koehler 1981; Peters and von den Driesch 1997). Also clay figures of cart-drawing camels of the same period from Ulug Depe (Turkmenistan) imply a use of domesticated camels as draft animals (Kuzmina 2008).

Given the presence of camel bones in Bronze Age strata from sites in Iran and southern Turkmenistan, it has been hypothesized that the inhabitants of the Iranian Plateau and the Kopet-Dagh-foothills area played a major role in the domestication of the two-humped camel (Benecke 1994).

Some archeologists and zoologists, however, do not believe that paleontological and archeological evidence from southwestern Central Asia can be interpreted as evidence for an ongoing process of domestication because there is not yet evidence for the presence of the wild *C. ferus* during the early to middle Holocene in this area. The authors argue that the center of domestication must lie further east, in areas where people were acquainted with the wild form over an extended period of time, perhaps in southern Kazakhstan or northwestern Mongolia (Peters and von den Driesch 1997). The sudden appearance of camel bones in Turkmen and Iranian archeological layers dated to the Bronze Age as well as the absence of skeletal remains of wild camels in earlier Neolithic strata in these regions suggest that people from the Kopet-Dagh foothills acquired the fully domesticated two-humped camels from eastern Asia. However, differentiation between wild and domestic camel bone material is difficult and the earliest evidence of fully domesticated camels from southern Kazakhstan and northwestern Mongolia dates to the second millennium BCE (Köhler 1981; Peters and von den Driesch 1997; Mukhareva 2007).

A recent genetic study of Late Bronze and Early Iron Age skeletal remains of *C. bactrianus* from Western Siberia and Southern Uzbekistan revealed homogeneity between modern domesticated camels from China and Mongolia and Bronze and Iron Age camels from Siberia and Uzbekistan. These results suggest that a single population was domesticated, though where that process took place remains uncertain. Furthermore, sequences of the extant wild camel are phylogenetically extremely distant to domestic two-humped camels, pointing to a population split long before domestication (Trinks et al. 2012).

Canada: Cultural Heritage Management

David Pokotylo[1] and Andrew R. Mason[2]
[1]Department of Anthropology, University of British Columbia, Vancouver, BC, Canada
[2]Golder Associates Ltd., Burnaby, BC, Canada

Introduction

While cultural heritage encompasses tangible and intangible aspects of past and contemporary cultures, here we focus on the management of places and material items of archaeological and historical significance in Canada, conducted in compliance with preservation laws. In Canada, legislative protection for cultural heritage resources reflects the division of powers split between federal and provincial-territorial governments. Since the 1970s, cultural heritage resources on most public and private lands have received some form of protection, although significant gaps exist for lands under federal jurisdiction (Pokotylo and Mason 2010). "Compliance" or "contract" archaeology is the most common practice of cultural heritage resource management conducted throughout the country.

Historical Background

The concern with cultural heritage resource management in Canada can be traced back prior to confederation of the country in 1867. As early as the 1850s, discoveries of archaeological sites during colonial expansion and the rise of relic hunting in eastern Canada prompted individuals, such as Sir Daniel Wilson and Sir John W. Dawson, and natural history societies to collect information on sites and encourage collectors to donate artifacts to museums (Trigger 1966a, b; Killan 1998: 16–7). The recovery of artifacts from a Montréal construction site by John Dawson in 1860 (Trigger 1966a) marks the birth of Canadian archaeology, and the earliest documented case of "rescue" archaeology in Canada.

The earliest legislation that was concerned with cultural heritage protection – the Indian Graves Ordinance – was enacted by the Colony of British Columbia in 1865. While some legislation for the protection and management of cultural heritage resources was present in the first half of the twentieth century (e.g., Quebec's 1922 heritage act, *Loi relative à laconservation des monuments etdes objets d'art ayantun intérêt historique etartistique*; British Columbia's 1925 *Historic Objects Preservation Act*; the Northwest Territories' 1930 *Ordinance Respecting the Protectionand Care of EskimoRuins*; and, Canada's 1930 *National Parks Act*), major developments did not occur until

the 1960s and 1970s. Charles Borden's 1951–1952 survey and salvage of archaeological sites threatened by damming of the Nechako River in central British Columbia, constituted the first formal mitigation project in Canada, and was the catalyst for British Columbia's *Archaeological and Historic SitesProtection Act* (1960) that became a model for many other provinces developing similar legislation in the 1970s.

Key Issues

Legal Framework of Cultural Heritage Management

Each province and territory in Canada has cultural heritage protection legislation, and an administrative unit to implement and manage activities resulting from it (Table 1). The administrative units charged with regulating work under these acts are situated in a variety of ministries or departments that often have a broader scope beyond cultural heritage. The basic principle of most of this legislation is to provide blanket protection for all cultural heritage remains and sites, on private or public property, recorded or not, and the use of permits or licenses to control any alterations to those sites. Although these laws vary, they share many common elements regarding the nature and kind of heritage resources protected, special protection provisions, control over the conduct of work, ownership and stewardship, management of impacts, and civil remedies for contravention. Penalties, which may include fines and/or incarceration, vary across the country with differentiation between individual and corporate violators.

While some federal legislation is relevant to cultural heritage resource protection (e.g., *Canadian Environmental Assessment Act*, *Canada Shipping Act*, and *Cultural Property Export andImport Act*), Canada is the only G8-nations member lacking comprehensive federal cultural heritage resource management legislation (Lee 2002). The Heritage Branch of the Department of Canadian Heritage addresses questions of cultural heritage policy and legislation and, with the Archaeological Services Branch of the Parks Canada Agency, has developed directives governing cultural heritage under the control of either Parks Canada or the Department (Parks Canada 2005). The Archaeological Services Branch is responsible for cultural heritage within Parks Canada lands and also responds to requests for advice from other federal government departments.

In the early 1990s, the Government of Canada outlined its plan to pass legislation to protect archaeological resources on federal lands, including First Nations reserve lands, across Canada. However, this plan never reached fruition. A number of reasons have been cited to explain this failure (see Burley 1994: 77–8), including First Nations' objection to Crown ownership of archaeological resources (Dunn 1991a: 1, 1991b: 3) and proposed powers of the federal government to unilaterally impose policy on Aboriginal archaeological resources (Dunn 1991b: 3). In 1999, the Canadian government initiated the Historic Places Initiative that included provision for a proposed "historic places act" to protect federally owned historic places, including archaeological sites, but such legislation has yet to be realized.

Cultural Heritage Management Practice in Canada

These mandates have changed the practice of archaeology in Canada over the last four decades. Most of the archaeological work conducted in the country is initiated by legislation and is associated with proposed development projects. The compliance process, irrespective of the specific legislation, consists of the following general steps:

- A proposed development is reviewed by the responsible government agency/agencies.
- This review may identify requirements for cultural heritage assessment studies.
- A qualified heritage consultant (typically private sector) is retained by the proponent and investigation permits are sought from government.
- Cultural heritage resource assessment studies are undertaken, followed by agency review and

acceptance of the study recommendations. Depending on the nature of the results, additional studies may be required.

The organizational structure of cultural heritage management varies across the country and jurisdictions. While some government agencies (e.g., Parks Canada 2005) undertake some of their own work, a substantial private-sector industry of cultural heritage professionals has emerged to deal with the explosion of cultural heritage resource management work in Canada (estimated to be in the tens of millions of dollars). In effect, the private sector acts as an extension of government in that it undertakes investigations to fulfill the requirements of legislation. The development of the private-sector industry has also resulted in the creation of professional organizations, mainly at the provincial level (e.g., British Columbia Association of Professional Archaeologists, Alberta Association of Consulting Archaeologists), but also at the national level (e.g., Canadian Association of Heritage Professionals), to support and self-regulate practitioners as well as to develop statements of ethics and codes of conduct specific to the needs of management-related activity.

Over the past two decades, an emerging disconnect between academic research and cultural heritage management has lessened in Canada. An increasing number of Canadian universities now offer relevant courses and programs to train future cultural heritage management professionals. Some governments (such as British Columbia and Alberta) have taken proactive steps to make grey literature more widely available to the cultural heritage community. Nevertheless, the sheer volume of material from development-driven work continues to present challenges to some museums serving as repositories for the resulting collections.

This legislation and resulting activity has also raised the public profile of archaeology, and the involvement of a variety of stakeholders in decisions on cultural heritage management. There is acknowledgement that public outreach and access

is essential to effective cultural heritage management. This has resulted in the increased development of interpretive centers based around archaeological sites, by First Nations, as well as provincial and federal agencies.

First Nations in Canada are increasingly demanding more control over their cultural heritage (Ferris 2003) and changes are occurring at different levels throughout the country. While there are some commonalities, interpretations of what cultural heritage resources are, and their values, can vary considerably among First Nations across Canada, and often differ from current definitions provided by government statutes. For example, many First Nations groups do not differentiate between archaeological sites, traditional use sites, or sacred sites. For proposed development projects in Canada requiring government permits or approval, there is a common law "duty to consult" with Aboriginal peoples, based on judicial interpretation of the obligations of the Crown (i.e., federal, provincial, and territorial governments) with respect to potential, or established, Aboriginal or Treaty rights of Aboriginal peoples. Cultural heritage issues now figure prominently in these formal consultative processes. In some provinces and territories (e.g., British Columbia and Northwest Territories), First Nations have input into the licensing-permitting process, while other jurisdictions (e.g., Nova Scotia, Ontario) stipulate that First Nations must be involved once aboriginal cultural heritage resources are identified in assessment studies. In response to the desire for greater control over their cultural heritage, an increasing number of First Nations groups have developed their own heritage policies and permitting systems to assert influence within their traditional territories. While not legally binding, the professional community has largely respected this parallel management regime. A number of memoranda of understanding have been signed between Aboriginal peoples, government, and industry for the management of cultural heritage resources on traditional lands (Budhwa 2005; Nelles and Alcantara 2011). Addressing the above issues remains a challenge, and requires continued dialogue with First Nations to find common ground.

Cultural heritage management in Canada involves government, Aboriginal people, cultural heritage professionals, and academics. The successful implementation of cultural heritage management requires all of these groups to recognize and respect the validity of each other's values to achieve what is essentially the same common objective.

Canada: Cultural Heritage Management and First Nations

David Pokotylo[1] and Andrew R. Mason[2]
[1]Department of Anthropology, University of British Columbia, Vancouver, BC, Canada
[2]Golder Associates Ltd., Burnaby, BC, Canada

Introduction

Canada is a large (9,984,670 sq. km) country with a population of approximately 34.5 million that includes 633 recognized First Nations; each of these aboriginal groups is distinctive with their specific cultural practices, language, and priorities. (Names are a problem and, in the case of Canadian Aboriginal people, have changed with the times. Although the Indian Act remains in force in Canada, the term "Indian" is widely disfavored by those whom the term is used to describe. "Native" (but not "Native Canadian") and "Aboriginal" are occasionally used in self-reference, but "First Nations" and "First Peoples" are more commonly accepted at present. As there is no universally accepted term or definition, these four terms are used interchangeably in this entry.) The present relationship between cultural heritage management (of which archaeology constitutes a major component, and is the main focus here) and First Nations in Canada is multifaceted. It is useful to review the historical background of its development to better understand the current context.

Historical Background

Archaeological evidence of aboriginal people's occupation of the lands now known as Canada extends back at least 12,500 years (and possibly to 28,000 years ago) (Goebel et al. 2008). Notwithstanding the eleventh century Norse settlement at L'Anse aux Meadows – the earliest evidence of European settlement in the New World – the French initiated colonization of the country in the sixteenth century. This was followed by British conquest and control in the mid-1700s, and then the confederation of several British North America colonies to form the country of Canada in 1867. The federal system of government that was established split many responsibilities of culture and heritage between federal and provincial-territorial governments that continues to the present. As the country expanded westward, the Canadian government continued the previous British colonial practice of military conquest and/or creating treaties with aboriginal people. Similar to other colonial countries, the federal government also attempted to assimilate aboriginal peoples through institutions such as Indian residential schools and legislation to systematically repress cultural expression (e.g., language, Potlatch and other ceremonial practices).

In the late 1800s, aboriginal lifeways throughout the country were viewed as disappearing in the face of territorial expansion. The Geological Survey of Canada's Anthropological Division was established in 1910, with a mandate to preserve information on aboriginal societies in Canada, and was housed in the newly established National Museum of Canada. While its focus was "salvage

ethnography," rather than archaeological sites (which were not considered endangered), Harlan I. Smith was appointed as the Survey's first archaeologist in 1911. Thus, Canada's first professional anthropologists and archaeologists were situated in federal government departments, rather than in universities in the country. While archaeologists such as Smith worked with aboriginal communities, aboriginal participation was usually limited to field assistance, such as finding sites and acting as informants about their contents. While this significantly contributed to the success of the fieldwork, aboriginal people had little if any input into the direct practice of the archaeological research, as well as actions affecting their cultural heritage (e.g., removal of totem poles, excavation of burials, building museum collections).

Up until the 1960s, archaeology in Canada continued in its infancy, with only a few people professionally involved in archaeological work in the country. The 1960s was a time of substantial growth and development, impacting cultural heritage resources across the country. Archaeologists in Canada faced the monumental task of establishing a baseline understanding of the country's archaeological record as it was being diminished by increasing land development. Prior to World War II, there was minimal provincial-territorial or federal legislation for archaeological protection (e.g., Quebec's 1922 heritage act, *Loi relative à la conservation des monuments et des objets d'art ayant un intérêt historique et artistique;* British Columbia's 1925 *Historic Objects Preservation Act*; the Northwest Territories' 1930 *Ordinance Respecting the Protection and Care of Eskimo Ruins*; and, Canada's 1930 *National Parks Act*). The federal *Indian Act*, dating back in various forms to 1927, provided some limited protection to some sites and objects (e.g., grave houses and poles, totem poles, petroglyphs) located on reserve lands, but aboriginal people had no direct involvement in establishing these protocols. Archaeological heritage protection legislation emerged in Canada in the 1960s in British Columbia, and then throughout the country in the 1970s. These laws and their policies focused on general mainstream societal values, and did not explicitly address concerns of the aboriginal communities whose ancestors were responsible for the majority of the archaeological record in the country. First Nations lacked authority to make, or provide input to, and exert control over the preservation and management of their heritage, although issuance of permits for archaeological work in the province of British Columbia and the Northwest Territories encouraged consultation with local First Nations communities, when applicable.

As cultural heritage legislation came into effect across the country, aboriginal people were mobilizing to press their case for self-determination and control over rights and representation, including traditional lands and cultural heritage. The initial catalyst was the federal government's 1969 *Statement of the Government on Indian Policy*, (Canada. Department of Indian Affairs and Northern Development (DIAND) 1969) that provoked aboriginal reaction and resistance that continues to the present. This has resulted in a series of landmark court cases that recognize inherent aboriginal rights in land and resources, the establishment of various kinds of aboriginal self-government, and negotiation of treaties in regions that previously lacked treaties. Of particular relevance to cultural heritage management is the Supreme Court of Canada's decision that the "Crown" (i.e., federal, provincial and territorial governments) has a duty to consult with First Nations and, where appropriate, accommodate their concerns when considering an action that may adversely impact potential or established aboriginal or treaty rights. In the context of such consultations, the prominence of cultural heritage matters is now reaching unprecedented levels and, for the first time, has the potential to significantly impact outcomes.

Key Issues

Milestone Events in Changing and Developing Relationships

Subsequent to the 1984 Declaration of Principles of World Indigenous Peoples (McGhee 1989: 15), First Nations in Canada have increasingly focused attention on their cultural heritage issues. Three

events have had a major impact on archaeology and museums in the country.

In 1988, the Lubicon Cree First Nation protest of *The Spirit Sings* exhibit of First Nations material culture at the Glenbow Museum in Calgary (during the Olympic Winter Games) had a profound impact on museums and First Nations relationships, particularly recognition that only aboriginal people can speak for themselves. The Lubicon Cree First Nation, and numerous other aboriginal groups, requested academics and museums to boycott the exhibit, claiming it fostered a colonial perspective of First Nations rather than presenting the contemporary context (see Harrison et al. 1988). At the same time, controversy arose at the Canadian Museum of Civilization in Hull, Quebec, during the planning of its First Nations Gallery. Numerous aboriginal organizations strongly protested the presentation of the Bering Land Bridge theory to account for the origins of First Nations peoples in Canada. This raised the issue of who "owns" prehistory, and the implications of archaeologists' research for First Nations communities (McGhee 1989). These events resulted in the establishment in 1990 of the joint Assembly of First Nations and Canadian Museums Association (AFN-CMA) Task Force on Museums and First Nations. The resulting *Task Force Report on Museums and First Peoples* recommendations included: equal partnerships to be forged between museums and aboriginal peoples, increased involvement of aboriginal people in museum work to improve representation and interpretation of their culture and history; improved access to museum collections for aboriginal people; and repatriation of artifacts and human ancestral remains (Hill and Nicks 1992). In a typically Canadian style, the Task Force elected not to recommend legislation to realize these recommendations (particularly repatriation) preferring to build partnerships, as legislation (such as the *Native American Graves Protection and Repatriation Act* (NAGPRA) enacted by the USA in 1990) was perceived as potentially obstructive to fostering positive relations.

The Royal Commission on Aboriginal Peoples (RCAP) report, resulting from a 1990 confrontation over a golf course development in Quebec that included a Mohawk cemetery, presented a series of recommendations on aboriginal self-government, health, education, treaties, heritage, lands, and resources (RCAP 1996). It included a reconfirmation of the significance of a "firm cultural base" in the general health and wellness of aboriginal communities and members (Royal Commission on Aboriginal Peoples 1996: vol. 3, 586–602), and considered aboriginal people to be "the owners of cultural sites" with "sole jurisdiction" over them (Royal Commission on Aboriginal Peoples 1996: vol. 2, 648–9).

In 1996, the Canadian Archaeological Association (CAA), the main national-level professional society in the country, formed a First Nations Archaeology Committee to review the relationship between First Nations and archaeologists and establish ethical guidelines and obligations for the profession. After extensive nation-wide consultation with the professional archaeological community and aboriginal people, the CAA prepared the *Statement of Principles for Ethical Conduct Pertaining to Aboriginal Peoples* in 1996 (Canadian Archaeological Association 1997). These principles acknowledge aboriginal people's interest in protection and management of the archaeological record, its interpretation and presentation; recognize the need to consult with aboriginal communities to negotiate protocols of archaeological practice; and encourage partnerships with aboriginal communities in archaeological research, management, and education, based on respect and mutual sharing of knowledge and expertise. However, these principles do not explicitly define the relationship between First Nations and their heritage with respect to physical or intellectual ownership rights, and are not explicit on how to evaluate the appropriateness of protocols of practice. In May 2000, the CAA further broadened its archaeological code of principles by adopting *Principles of Ethical Conduct* for the profession that state compliance with the *Principles Pertaining to Aboriginal People*.

While they do not carry the weight of law, many cultural heritage institutions and archaeologists in Canada have adopted recommendations from both the AFN-CMA and CAA documents as

guidelines in structuring their relations with First Nations, and these principles are changing the practice of cultural heritage research and management in the country. There are an increasing number of examples of shifts from policy to practice, as well as evaluations of the success of collaborations with First Nations communities (Holm and Pokotylo 1997; Hanna 2005; Rowley and Hauser 2008).

Issues and Challenges

Nevertheless, there remains a legacy of mistrust and apprehension among First Nations toward government, academic institutions, and the professional cultural heritage community that needs to be addressed. Major continuing concerns include: repatriation of both ancestral human and cultural remains, representation of First Nations culture and history, dissatisfaction with existing cultural heritage protection legislation, authority in stewardship, and participation in the protection of cultural heritage and the care of collections (see Nicholas 2009).

Repatriation has now been a pressing issue for over three decades in Canada. It was first raised as an issue at The Canadian Museum Association consultations with the Assembly of First Nations at the 1988 "Preserving Our Heritage" conference (McGhee 1989: 15). In 1990, the CMA-AFN Taskforce concluded that it was better to handle repatriation efforts on a case-by-case basis. At present, there is no national repatriation legislation, although one exists at the provincial level: Alberta's *First Nations Sacred Ceremonial Objects Repatriation Act* was enacted in 2000. The recent CAA guidelines, in conjunction with provincial and territorial permitting requirements, have resulted in a decreased number of human remains coming into museum and repository collections. Successful repatriation efforts (see Hanna 2005; Rowley and Hauser 2008) have been carried out under the AFN-CMA general guidelines, and protocols established by individual "ad hoc" museum polices that vary across institutions.

Issues of representation have become a focal point in discussions between Canadian museums and First Nations. Historically, the representation of aboriginal people within a museum context was characterized by little meaningful collaboration and involvement by aboriginal people. There has been a significant shift in the nature and scope of collaboration for aboriginal people to be able to represent themselves and their own histories (see Holm and Pokotylo 1997), as well as efforts to increase dissemination of knowledge to aboriginal peoples to make more informed decisions about the management, research, and presentation of their past and culture (see Rowley et al. 2010).

First Nations have raised objections to existing cultural heritage protection legislation, as well as the absence of federal legislation – Canada is the only G8-nations member lacking comprehensive federal cultural heritage resource management legislation (Pokotylo and Mason 2010). In the absence of federal legislation, the Archaeological Services Branch of Parks Canada is responsible for cultural heritage within Parks Canada lands and responds to requests for advice from other federal government departments. Although, the Canadian government in 1999 took steps to establish a proposed "historic places act" that involved consultation with First Nations, legislation is not yet forthcoming. There are increasing demands by First Nations for control over their heritage, but present heritage preservation acts are still not explicit about Native ownership of their archaeological heritage. An initiative to pass federal legislation in the 1990s was unsuccessful, due in part to First Nations' objection to government ownership of archaeological resources (Dunn 1991: 3; Bell 1992: 482) and proposed federal powers that would unilaterally impose policy on aboriginal archaeological resources (Dunn 1991: 3). Given recent Canadian Supreme Court rulings that reaffirm the principle of fiduciary responsibility to protect the interests of aboriginal people, some archaeologists suggest there is a basis for arguing a case for a fiduciary obligation on the part of the Crown to care for aboriginal heritage sites and material (Ferris 2003).

Recent amendments to some provincial-territorial legislation provide greater direct aboriginal involvement and decision-making. In some provinces and territories (e.g., British Columbia and Northwest Territories), First Nations have

input into the licensing-permitting process, while other jurisdictions (e.g., Nova Scotia, Ontario) stipulate that First Nations must be involved once aboriginal cultural heritage resources are identified in assessment studies. Given the desire for greater control over their cultural heritage, an increasing number of First Nations groups are developing their own heritage policies and permitting systems to assert influence within their traditional territories (e.g., Nicholas 2009). While not legally binding, the professional community has largely respected this parallel management regime. As well, more First Nations groups are hiring their own heritage specialists to inventory, research, and manage their own cultural heritage resources. These initiatives are establishing First Nations as not just collaborators, but cultural heritage managers, in provincial-territorial management schemes. An increasing number of memoranda of understanding are also being signed between aboriginal peoples, government, and industry for the management of cultural heritage resources on traditional lands.

Interpretations of what cultural heritage resources are, and their values, can vary considerably among First Nations across Canada, and often differ from current definitions provided by government statutes. For example, many First Nations groups do not differentiate between archaeological sites, traditional use sites, or sacred sites and object to the narrowly defined scope of cultural heritage assessments, given adherence to legislation, that often exclude traditional use sites and sacred sites to provide a more representative perspective of past aboriginal land use. Assessing the significance of aboriginal cultural heritage sites is also a major concern – although First Nations values are on the list of significance evaluation criteria, there is often criticism that Western perspectives and scientific values weigh heavily in the evaluation process, particularly in cases where there is little material evidence. This is compounded by concern over the relative ranking of significance of heritage resources that contradicts aboriginal perspectives that all ancestral sites are significant. Both provincial-territorial and federal heritage policies are starting to address this, but aboriginal knowledge and value systems need to be incorporated to effectively remedy the problems.

Future Directions

Although we have identified above many issues in the relationships of First Nations and Canadian heritage institutions and professionals involved in the research and management of aboriginal cultural heritage in Canada, and challenges to be faced, we can also point to positive developments. Over the past two decades, there has been a slow but progressive shift toward partnership and collaboration based on mutual respect and shared responsibility. Some examples are noted here. Although the country still lacks comprehensive federal heritage legislation, the Canadian government has placed greater emphasis on commemorating aboriginal heritage sites nationally and internationally (as World Heritage Sites) to correct imbalance in representation of the pre- and post-contact heritage of the country, and a number of aboriginal sites are currently on Canada's World Heritage Site tentative list.

In British Columbia, few treaties were negotiated at the time of colonial settlement, and negotiation land claims remain a major political issue. Over the past two decades, archaeologists are increasingly working closely with First Nations, who have recognized the potential contribution of archaeology in presenting their court cases for continuous occupation of unceded traditional lands (see Nicholas 2006). Over this same time period, there have been a number of Treaties signed with British Columbia First Nations that include provisions for cultural heritage resources. For example, with the Nisga'a Nation, cultural resources are addressed in a comprehensive fashion. In Chapter 17, Protection of Heritage Sites (Sections 36 to 39), of the *Nisga'a Final Agreement* (Nisga'a Nation et al. 2000), the treaty allows the Nisga'a Nation to develop their own processes to manage cultural heritage sites on Nisga'a lands. Further, the treaty states that the government of British Columbia will develop or continue processes to manage heritage sites until the Nisga'a Government establishes their own

policies. In other words, the treaty allows the Nisga'a to develop their own heritage protection processes, and until such time that this has been implemented, the provincial status quo is maintained.

First Nations have more influence, power, and involvement in cultural heritage matters than they did just a few years ago, given recent court decisions on the "duty to consult" that brings First Nations to the negotiating table. They are taking on a major role in the management of heritage resources within their traditional territories. There is also an increasing level of day-to-day inclusion and involvement of aboriginal people on cultural heritage management projects (although this varies dramatically across the country); this can range from acting in the capacity of "site monitors" representing First Nations' interests, "field assistants" providing assistance with the field investigations up to the level of principal investigator. While things are getting better, there is still a considerable way to go for First Nations to assume a major participatory and authoritative role in the management process, and formal transfer of responsibility has just begun to be realized in cases of treaty settlement lands (Grier and Shaver 2008).

Increased educational opportunities for aboriginal peoples, particularly in post-secondary education, have now resulted in the emergence of Canadian-educated First Nations cultural heritage specialists who now hold positions ranging from heritage consultants working for First Nations and private industry to university faculty. This is having an impact on capacity-building within First Nations communities, provides a stronger aboriginal perspective in cultural heritage management practice, and, ultimately, contributes to methodological and theoretical developments within the discipline (e.g., Yellowhorn's 2002 "Internalist Archaeology",) as Indigenous Archaeology (Nicholas 2010) becomes a distinct recognized subdiscipline.

Looking to the future, we can expect a greater convergence of government legislation and policy that addresses First Nations' interests, values, and priorities, and greater participation and influence of First Nations in the cultural heritage resource management process. New treaties will likely follow the precedent of including provisions to transfer control of day-to-day management of cultural heritage sites on treaty settlement lands. Cultural heritage professionals and institutions will continue to be proactive in developing meaningful partnerships with First Nations communities that realize increased aboriginal power in the design, conduct of cultural heritage research and management. The rate of this change will be determined by attitudes of provincial-territorial and federal governments, First Nations' capacity-building, and their ability to take the time to address the question of cultural heritage resources in the face of other competing priorities such as health care, housing, and employment.

Canada: Cultural Heritage Management Education

Joanne Lea
Lakehead University, Huntsville, ON, Canada

State of Knowledge and Current Debates

Introduction: Canada

Canada is the northern nation in North America. People arrived in the territory now called Canada in waves. Archaeological evidence suggests this began perhaps 30,000 years ago with First Nations (Wright 1976). Europeans such as Scandinavians (about 1000 years ago), French, and finally British (from 500 to 100 years ago) colonized the land. Four British colonies joined and Canada became a nation in 1867. The nation has continued to develop to have ten provinces and three territories.

Introduction: Cultural Heritage Management in Canada

The large area and the history of the country fragmented cultural heritage management policy and practice across Canada. Heritage policies changed with the development of the nation. Now, stewardship of and education about Canada's archaeological heritage work to protect heritage and strengthen the diverse cultural identities of Canadians.

Initially, a federal system of government was adopted. This established that the federal government was responsible for cultural heritage on federal lands and on First Nations' lands as per treaties. The federal government was also responsible for the international trade in cultural heritage. Provincial (now 10) and territorial (now 3) governments had jurisdiction over education and culture otherwise.

Under the Canadian government's "National Policy" of economic development and territorial expansion in the late nineteenth century, the recording and display of (then) present and past lifeways of First Nations peoples were undertaken before their assumed assimilation. The National Museum of Canada was founded in 1911 and became the home for this work, undertaken by Canada's first archaeologist Harlan I. Smith and first anthropologists, Edward Sapir and Marius Barbeau (Dyck 1998, 116).

Barbeau's close work with American anthropologist Franz Boas began the influence of American anthropological theory on Canadian cultural heritage management both federally and in the developing provincial museums. Change would begin in the 1960s.

The first Canadian Archaeology department (not as part of Anthropology) was opened at the University of Calgary in 1964. Canada's first Canadian-trained PhD in Archaeology graduated in 1967 (Mackie 1995, 181–182). That year – 1967 – was the centenary of Canada's birth as a nation, and the focus on and funding for Canada's heritage expanded. Since then, numerous programs in Canadian universities and colleges are offered in archaeology and studies related to heritage management (see Tables 1 and 2).

Canadian archaeologists, mostly at the National Museum, organized themselves into the Canadian Archaeological Association (CAA) in 1969 (Simonsen 1996, 1) and began publishing the *Canadian Journal of Archaeology*. The Archaeological Survey of Canada (ASC) was created out of the archaeological staff of the National Museum of Canada to work on federal lands. First Nations did not have input into policies concerning their lands (Arawack 1986). Parks Canada had the mandate for archaeological work

at National Historic Sites and National Parks (Burley 1994, 83). There was therefore a de facto split, with the CAA and ASC focused on precontact (i.e., of First Nations with Europeans) and Parks Canada focused primarily on post-contact archaeology.

The federal government decentralized its offices from the capital of Ottawa to create regional centers in 1970. In 1971, funding and policy favored the establishment of museums across Canada, not just in major centers (Dixon et al. 1974, 2). Federal legislation was drafted to deal with international import and export of antiquities (*Import and Export Act* RSC 50.51 1974-75-76 Canada).

Also in this period after 1945, avocational or nonprofessional archaeological groups developed formally across the country (see Table 3). At about the same time, professional, contracted "cultural resource management" archaeology companies were also developing, mostly in urban areas to work with archaeological heritage threatened by building and development. This urban work, or work at historic sites, took place in the public eye, with increasing public interest and involvement.

Theoretically, Canada was pursuing a cultural-historical approach to archaeology with a focus on First Nations' cultures. In this environment, Canadian archaeologists sometimes avoided American

theory to assert Canadian national identity, and some stated that fieldwork could be the same as theory (Kelley and Williamson 1996, 10).

Key Canadian archaeologists working on post-contact urban sites began to develop public programming to create a sense of stewardship and belonging in order to protect the archaeological heritage. However, they found neither a theoretical base nor professional acceptance for their work in Canada and so sought these outside the country.

For example, Paul Erickson of Nova Scotia, founder of the *Teaching Anthropology Newsletter*, worked through the American Anthropological Association (AAA); Québec archaeologists from Montréal and Québec City made contacts with other urban archaeologists at the Society for Historical Archaeology (SHA); Karolyn Smardz (now Smardz Frost) of Toronto and Heather Devine of Alberta joined the Society for American Archaeology (SAA) Public Education Committee. Smardz also worked closely with Stone and the World Archaeological Congress (see Stone and Mackenzie 1990, 293–307).

These archaeologists became the vanguards in Canada for American and British archaeological theory such as critical theory (see Leone and Potter 2003) or interpretive archaeologies (see Hodder 1991, 2000) and the practice that was becoming known as public archaeology. These pioneers of public archaeology in Canada established influential programs and resources such as Paul Erickson's *Teaching Anthropology Newsletter*, the Reseau Archéo-Québec, and the Pointe-à-Callière Museum. Devine authored teaching resources, and Smardz founded the Archaeological Resource Centre for the Toronto Board of Education and published widely for a broad audience. Pokotylo and Guppy (1999) and Pokotylo (2002) jointly authored and wrote

studies about Canadian attitudes to archaeology, founded a graduate course in Public Archaeology at the University of British Columbia and, as joint chair of the CAA, worked to establish a statement of Principles for Ethical Conduct Pertaining to Aboriginal Peoples (see www.canadianarchaeology.com/caa/about/ethics).

From these efforts, the groundwork was laid that gained acceptance for public archaeology in Canada so that interpretation and education programming about archaeological heritage has become part of cultural management across Canada. Public archaeology programming was mandated at Parks Canada sites, under Parks' Guiding Principles (see Canada 1994) although dramatically affected by budgetary cuts to programs and recentralization of collections from regional centers in 2012. It is found at Canadian museums and as part of provincial policy for licensing and permitting of archaeological research. Some exemplary programs and resources that developed are listed in Table 3.

Definitions

The aspect of Cultural Heritage Management Education known as public archaeology, as practiced in Canada is multifaceted. It grew from the definition coined by McGimsey (1972, 5).

Under the umbrella term of "Archaeology Education," stemming from Smardz and Smith's *Archaeology Education Handbook* (2000), public archaeology is seen to include the following: teaching about archaeology in formal education systems, elementary, secondary, and post-secondary; undertaking archaeology programs in museums, at archaeological and historic sites; publishing and creating media productions for

wide public audiences; and lobbying politically for changes to heritage legislation.

As well, community archaeology programming is undertaken, following the model of an empowered public directing archaeological research (as per Pope and Mills 2004).

The public for public archaeology in Canada is also multifaceted and reflects McManamon's (1991, 121) use of the term "publics" to indicate various stakeholders in archaeological heritage. As an officially multicultural country (as per the Canadian Multiculturalism Act RS 1985 c. 24), Canada is incorporating the multivocal and inclusive approach of public archaeology. This includes the reclamation of identities by colonized peoples (see Cooper and Stoler 1997, 31), the foundation for a sense of belonging for immigrants, and the development of regional economies through sustainable tourism.

Debates and Future Directions

There remain areas to be addressed in Cultural Heritage Management Education (CHME) in Canada. There is the lack of a national forum for Cultural Heritage Management Education. There is no national professional body for CHME work, despite some CAA work. The Canadian Association of Heritage Professionals provides opportunities for professional colleagues to meet and pursue professional development. However, there is no national forum in which to link provincial or territorial and avocational groups, and there is no national heritage legislation. This has led to duplication of programming and services unknown to each other across the country and to uncertainty about federal oversight or protection of archaeological heritage that is not located on federal lands or on First Nations' territories.

With regard to First Nations' cultural heritage management, the Canadian Museums Association (CMA) only began consultation in 1988 with the Assembly of First Nations. Consultation continued at the 1991 Aboriginal Archaeology Symposium at the Canadian Museum of Civilization and at the CMA's Curatorship and Indigenous Perspectives in Postcolonial Societies Conference in 1996. That year also the CAA adopted its Principles for Ethical Conduct Pertaining to Aboriginal Peoples.

By 2006, the CAA hosted meetings on Evolving Discourses in Indigenous Archaeology in Canada and, by 2009, elected a member of a First Nation as CAA president.

The role of First Nations in protecting and interpreting their own archaeological heritage is a developing aspect of CHME. The *Calls to Action* report, released in 2015 by the Truth and Reconciliation Commission in Canada, and the United Nations Declaration on Rights of Indigenous Peoples (2008) increasingly inform legislation, policy, practice, and education regarding archaeology, cultural heritage, and heritage management.

While CHME has become a recognized aspect of archaeological research in Canada, there remain areas of political will and legislated change that are required to include all Canadians fully in the management of their archaeological heritage.

Canada: World Heritage

Andrew R. Mason[1] and David Pokotylo[2]
[1]Golder Associates Ltd., Vancouver, BC, Canada
[2]Department of Anthropology, University of British Columbia, Vancouver, BC, Canada

Introduction

The Convention Concerning Protection of the World Cultural and Natural Heritage (the World Heritage Convention) was adopted by UNESCO Member States in 1972 and entered into force on December 17, 1975. The World Heritage Committee and World Heritage Fund became operational in 1976.

There are three official scientific advisory bodies to the UNESCO World Heritage Committee: (1) the International Centre for the Study of the Preservation and Restoration of Cultural Property (ICCROM), an intergovernmental organization dedicated to the conservation of cultural heritage; (2) the International Council on Monuments and Sites (ICOMOS), a nongovernmental organization that provides expertise and evaluation of cultural properties nominated for inscription on the World Heritage List; and (3) the International Union for Conservation of Nature (IUCN), an organization comprised of member states and civil society organizations that provide expertise and evaluation of natural properties nominated for inscription on the World Heritage List (Cameron 1990).

Objectives of the World Heritage Convention include "…identification, protection, conservation, presentation and transmission to future generations of cultural and natural heritage of outstanding universal value" (UNESCO 2017a: 10). The core concept of "outstanding universal value" (OUV) is defined as "…cultural and/or natural significance which is so exceptional as to transcend national boundaries and to be of common importance for present and future generations of all humanity" (UNESCO 2017a: 19). The protection of heritage sites of such significance is the responsibility of the international community and by becoming a State Party to the World Heritage Convention, countries are obligated to fulfill this mandate (UNESCO 2017a).

Historical Background

In 1972, Canada sent federal government representatives, from Parks Canada, as delegates to the World Heritage Convention founding meetings in Paris, and on July 23, 1976, Canada became a State Party to the World Heritage Convention (Pinkerton 2010). Parks Canada was designated as the lead agency to implement the Convention in Canada – a role that continues to this day. This responsibility of Parks Canada is a logical extension of its original mandate defined in 1930, when Canada's parliament passed the *National Parks Act* that created Parks Canada to protect and develop areas of

national significance to Canada's natural and cultural heritage (Lothian 1976, 1977, 1979, 1981).

Canada has played a prominent role in the development and implementation of the World Heritage Convention from its origins to the present day. To date, at least three Canadians have served as Chair of the World Heritage Committee. Equally important is Canada's leadership in technical and advisory aspects of the World Heritage Convention for both natural heritage and cultural heritage. For example, Canadians have held prominent roles within ICCROM, ICOMOS, and the IUCN.

Canada's date of adhesion to ICCROM was July 11, 1978, and numerous Canadians and Canadian agencies have provided resources, leadership, and technical expertise to this organization. An example acknowledging the leadership role played by Canadian heritage professionals in ICCROM was UNESCO's nomination in 2011 of Carleton University Professor Herb Stovel for the prestigious ICCROM award. This award recognizes exceptional contributions to the conservation community and is given to individuals who have made significant contributions in the field of conservation, protection, and restoration of cultural heritage.

With respect to cultural heritage, Canadians have held the position of Secretary General and Director for the ICOMOS Secretariat in Paris, including the early years (1979–1983) following the implementation of the World Heritage Convention (see LeBlanc 1984). Other Canadians have served as ICOMOS World Heritage Advisors, chaired expert meetings, and played a crucial role in the development of doctrinal texts such as the Appleton Charter for the Protection and Enhancement of the Built Environment (1983).

With IUCN, Canadians have held several prominent roles (including Director General). In the early years of the World Heritage Convention, Parks Canada's Chief of Planning (Harold Eidsvik) was seconded to IUCN in Switzerland (1977–1980) and elected Chair of what is now the World Commission on National Parks – the unit of IUCN then responsible for the World Heritage Convention. Other Canadians have served as Executive Officer for IUCN's commission on National Parks and Protected Areas and Senior Advisor to IUCN's World Heritage Committee.

At the first meeting of the World Heritage Committee, where the initial sites were inscribed on the World Heritage List (1978), the Canadian government nominated two sites: Nahanni National Park Reserve in the Northwest Territories, based on natural criteria, and L'Anse aux Meadows National Historic Site in Newfoundland, based on cultural criteria. This latter site was actively being investigated at that time and is the earliest known European settlement in the New World, dating to ca. A.D. 1000.

As of June 2018, Canada has 18 World Heritage Sites (10 based on natural criteria, 8 based on cultural criteria) (Table 1). Of the eight cultural sites, six represent post-contact settler history (one French, two English, one Norse, one Acadian, and one Basque); the other two commemorate both pre- and post-contact Indigenous cultures (Haida and Blackfoot). Two of these sites, Waterton-Glacier International Peace Park and Kluane/Wrangell – St. Elias/Glacier Bay/Tatshenshini-Alsek, are examples of international cooperation where existing Canadian and American national parks were jointly proposed to the World Heritage Committee for World Heritage Site status (UNESCO 2016).

Canada's Tentative List was updated in 2017 (Table 2). Of the 14 sites, 2 are based on natural criteria, 7 on cultural criteria, and 5 on both cultural and natural ("mixed") criteria. Of the cultural sites, 11 represent Indigenous cultures.

Key Issues/Current Debates

At the time of writing, one inscribed site and one site on Canada's Tentative List are the subject of ongoing debate. The issues surrounding these two sites are discussed as follows.

Wood Buffalo National Park World Heritage Site

In 2014, the Mikisew Cree First Nation submitted a petition to the UNESCO World Heritage Committee asking for Wood Buffalo National Park World Heritage Site to be added to the List of World Heritage in Danger (Mikisew 2014). The petition cited a number of concerns related to the

impact of hydroelectric dams, oil sands development, and climate change that could adversely impact the site's OUV.

In 2015, the World Heritage Committee requested that Canada host a reactive monitoring mission and undertake a strategic environmental assessment (SEA) to assess the potential cumulative impacts of all developments on the site's world heritage values. Subsequently, in the fall of 2016, Parks Canada facilitated a joint World Heritage Centre and IUCN reactive monitoring mission that sought to understand and discuss the impacts of upstream developments on the park's world heritage values. The mission report, including 17 recommendations, was released in March 2017 (UNESCO and IUCN 2017).

For the SEA, Parks Canada retained a consortium of external consultants to undertake the study and set an April 2018 deadline. This assessment sought to examine activities and trends that may have adverse effects on the environmental condition of the World Heritage Site. Specifically, the study focuses on an assessment of the cumulative effects of development on the features and species integral to the park's OUV. The report was released in May 2018 and includes 44 recommendations to restore management objectives that are not being met and to address gaps in information. Data indicate that management objectives for the karst, salt plains, and Great Plains boreal grasslands are being met. With respect to the Peace-Athabasca Delta, changes in the hydrological regime have adversely affected the quantity and quality of habitat for waterfowl. The ability of Indigenous peoples to practice their traditional way of life is being adversely impacted, and desired outcomes for the world heritage values are not being met (IEC 2018).

Consistent with the World Heritage Committee's 2017 decision on the State of Conservation of Wood Buffalo National Park World Heritage Site (UNESCO 2017b), Canada is in the process of preparing an action plan for December 2018 that coordinates with other planning processes and involves affected Indigenous groups and stakeholders. The action plan will be informed by the recommendations of the reactive monitoring mission and by the findings of the SEA.

Pimachiowin Aki

For the site of Pimachiowin Aki, the World Heritage Committee deferred the initial bid in 2013 after two advisory groups said it was unclear what made the area unique and requested more information. Pimachiowin Aki was proposed again in 2016 and once more deferred. In this instance, one of five First Nations communities involved in the project – Pikangikum – pulled out. Pikangikum leaders were upset over the way their treaty rights were described. A third bid has now been submitted to UNESCO and is expected to be considered in the summer of 2018. Without Pikangikum's involvement, the proposed area has been reduced slightly from its original 33,400 km^2 (Lambert 2017).

As for the remainder of the tentative sites, the Canadian government is preparing nomination dossiers, and sites will be brought to the World Heritage Committee in due course. For existing World Heritage Sites in Canada, as in most other countries, funding and land use pressure are current and future issues that need to be addressed. The latter is particularly acute in the Canadian Rocky Mountain Parks World Heritage Site where there is a strong demand for visitor amenities, employee accommodation, and associated infrastructure. Limits on available funding and land use pressure can potentially erode the integrity of the listed sites. This is a common challenge for many World Heritage Sites throughout the world, although Canada's sparse population (37 million, largely concentrated along its southern border with the United States) and sheer size (9,984,670 km^2) exacerbate this problem.

Representativeness of Canada's World Heritage Sites is certainly a challenge for the country. Canada is a massive country with huge natural and cultural diversity. The French–English dichotomy of Canada is well known, but there also is the mosaic of cultures reflected in Canada's other immigrant population and the 633 recognized, distinct Indigenous groups in the country. While this diversity constitutes a great wealth, it also creates an obligation to guard against bias in selection of cultural sites for nomination (e.g., non-Indigenous/Indigenous or French/English) and the need to engage and

collaborate with these and other groups on nominations put forward for consideration (Pinkerton 2010). The province of Prince Edward Island is not represented in Canada's World Heritage Sites (existing or on the Tentative List).

Future Directions

Canada's existing and Tentative List of World Heritage Sites demonstrates there are sites in Canada with OUV warranting commemoration on the world stage. This includes natural and cultural heritage worth recognizing, rather than just emphasizing natural history which is a common Canadian stereotype. As reflected by the Tentative List, natural history, wildlife, and Indigenous and non-Indigenous cultures will be acknowledged. The Tentative List includes mixed nominations (cultural and natural criteria) as well as less common "types" of cultural heritage (e.g., cultural landscape). These are positive signs and reflect a certain maturity in Canada's approach to world heritage (see Pinkerton 2010: 29).

Although Parks Canada does not have an overarching strategic plan for the World Heritage Site nomination process, Canada updates its Tentative List every 10–15 years. There is no attempt to ensure a regional balance or ratio between cultural and natural sites. Day-to-day activities follow established world heritage policy and schedules (e.g., state of conservation reporting, annual committee meetings, clear processes and timelines for submission and review of nominations). In all likelihood, Canada will continue to work through its portfolio of tentative sites with new sites added as considered appropriate and resources allow. For its existing World Heritage Sites, Canada will continue to treat these sites with the respect they deserve and will address management challenges as they emerge to the best of its ability (see Pinkerton 2010: 25). Canadian heritage professionals will undoubtedly continue the legacy of providing expertise and leadership in the arena of world heritage for many years to come, either as private individuals or with organizations such as ICCROM, ICOMOS, and IUCN.

Canadian Archaeological Association (CAA)

Eldon Yellowhorn
Department of Archaeology, Simon Fraser University, Burnaby, BC, Canada

Basic Information

Anthropologists, such as Franz Boas, once thought that grave robbing was an appropriate research method. While on a collecting expedition near Victoria, British Columbia, he regularly sought out Indian graves and collected any bones and artifacts he found (Cole 1999). Of course he was not alone in that endeavor as people had been looting Indian cemeteries long before Boas visited the northwest coast. During the Gold Rush days, in 1865, the Crown Colony of British Columbia enacted the *Indian GravesOrdinance; An Ordinance to Prevent the Violation of Indian Graves*, which prohibited the taking of property that the Crown claimed as part of the public domain. The penalty for breaking this law was a fine and imprisonment. Given its intent and what it reveals about research methods then in vogue, ethical practices could only evolve and improve.

Over a century later, in 1968, archaeologists reached a milestone when they created the Canadian Archaeological Association (CAA) to be their national voice. Prior to that, they had only organized on the provincial level. Such was its fledgling status that some years would pass before ethics became a subject in their profession's conversation, though the topic did simmer. At a symposium organized by the Royal Society of Canada, in 1976, ostensibly convened to discuss new perspectives in Canadian archaeology, any mention of ethics was notably absent. Only Basil Johnston, an Ojibway who worked as an ethnologist at the Royal Ontario Museum, directly addressed the issue of museums, human remains, and ethical research. He expressed his concern at a time when Native people were reacting to government policy and finding their own voice in the nation's politics (McKay 1976).

Major Impact

Native activists of the 1970s and 1980s advanced the cause more forcefully until their efforts began to elicit a dialogue with the archaeological community. They protested that the treatment of human remains inflicted harm on Aboriginal people by putting their ancestors on display as if they were mere specimens. They argued that their heritage should not be routinely exhumed with methods that represented an arrogant display of power. Moreover, judgments from the Supreme Court after 1982, when Aboriginal rights were included in the modern constitution, generally made Canadians aware that these rights had to be accommodated. Thus, by the beginning of the 1990s, the trajectories of archaeological research and Aboriginal rights discourse were finally intersecting. Changes in public policy began to affect matters within the profession too, though the dialogue showed more influence from legal precedents and public laws than ethical considerations. Negotiated settlements for comprehensive land claims in northern Canada shed more certainty on the rights of Aboriginal people to control their own heritage. Once passed through the parliament, they became legal documents with the full weight of federal law and subsequent agreements, all containing similar articles clarifying that process. Coeval with these developments, the Social Sciences and Humanities Research Council announced that it would put more emphasis on ethical research and would consider only research proposals that had passed ethical review.

Against this backdrop, the CAA acknowledged that it could no longer avoid issuing a statement to direct its members when communicating with Aboriginal peoples. In 1992, with a

grant from the federal government's Department of Communication, the CAA began a consultative effort to define guidelines for its membership. The executive created an ad hoc committee called the Aboriginal Heritage Committee, which had members from all regions of the country and Aboriginal communities. Its terms of reference were to organize regional meetings and to solicit input from as many stakeholders as possible. To this end, the members sought the advice of varied individuals and groups on the issues to be included in a draft statement that would be brought to the general membership. After 2 years, the draft, Statement of Principles for Ethical Conduct Pertaining to Aboriginal Peoples, was completed and articulated 12 core principles organized around four themes. CAA members debated the draft statement at their annual meeting in 1994 and voted by a substantial margin to accept it. The full text was published in the Canadian Journal of Archaeology in 1997 (CAA 1997; see also Rosenswig 1997 and Wylie 1997).

Canarian Indigenous People

A. José Farrujia de la Rosa
Universidad de La Laguna, Santa Cruz de Tenerife, Spain

State of Knowledge and Current Debates

The Canarian Indigenous people is the name given to the early inhabitants of the Canary Islands, an archipelago located on the Atlantic ocean, just 100 km (62 miles) off the southern coast of Morocco, and integrated by eight islands (from West to East: El Hierro, La Palma, La Gomera, Tenerife, Gran Canaria, Fuerteventura, Lanzarote, and La Graciosa).

Regarding the origins of this population, and according to archaeological research, the Imazighen (Berbers) from North Africa settled in the Canarian Archipelago at the beginning of the 1st millennium BC (Atoche Peña 2011) and developed a culture on the islands that can be linked to native North African societies and magical-religious practices associated with the religions of the ancient Amazigh (singular word for Imazighen) (Hachid 2000).

The Canarian Indigenous people lived mainly in natural caves (and to a lesser extent in man-made caves cut into rocks), usually near the coast, 300–500 m above sea level. These caves were

sometimes isolated but more commonly formed settlements, with burial caves nearby. Gran Canaria is the only island where settlements with stone houses forming important urban concentrations can be found, although isolated houses have also been documented. In terms of subsistence, animal husbandry was the main means of support for Indigenous societies in the different islands, with the exception of Gran Canaria, where agriculture was more developed, including both dry and irrigated farming. The herds basically consisted of goats and sheep and, to a lesser extent, pigs. Gathering plants and fishing also provided significant food resources.

Ceramics are the utensils most commonly found in archaeological excavations, and also the most widely studied, due to the possibilities they offer, on the basis of a cultural-historical approach (which still prevails among Canarian archaeologists), for establishing timelines, food consumption patterns, stylistic trends, etc. In the Canary Islands, they are typically varied, with each island presenting both formal and decorative differences. The only common feature is that they were made without the use of a wheel, since Indigenous ceramics were handmade, by forming the base first and then gradually shaping the sides of the container using small cylinders of clay. Ceramic items were often decorated with indentations or incisions or polished, in particular in Gran Canaria, where painted decorations in shades of red, black, and white were also common. The La Palma ceramics are characterized by its rich relief (incised-impressed) decoration, very different to the ceramics from the other islands, and they provide the best stratigraphic sequence, which has four phases, although the Gran Canaria ceramics are undoubtedly the most complex, due to the variety of shapes, handles, and decorative features. They also reveal the clearest affinities with North African Amazigh ceramics. The shape of the Tenerife ceramics enables parallels to be drawn with those documented in Mauritania and in the central and southern Sahara regions.

The raw materials used in the lithic industry were obsidian and basalt, and the most common tools were burins, borers, and scrapers. The most typical polished stone items were millstones, used to grind cereals. In terms of the bone industry, which was based mainly on ovicaprine bones, grainers and awls for use in leatherwork were common, as well as fishhooks. Antlers were also used to make tools for plowing or were set in wood to be used as projectiles (spears). There was also an important wood industry, essentially represented by shepherd's crooks, combs, shields, containers, and doors for man-made caves and houses.

The majority of the plant fibers used by the Canarian Indigenous people for clothing and basketmaking came from rushes (*Holoschoenus vulgaris*), which were used to make mats, baskets, bags, and shrouds, as well as garments, which were also manufactured from goatskin.

In terms of social and political organization, there was a system of matrilineal descent in most of the islands, in which inheritance was passed on via the female line. Social status and wealth were hereditary and determined the individual's position in the social pyramid, which consisted of the king (known as the *Guanarteme* in Gran Canaria and *Mencey* in Tenerife), the relatives of the king, the lower "nobility," villeins, plebeians, and, finally, executioners, butchers, embalmers, and prisoners (Farrujia 2014).

With regard to faith, the Canarian Indigenous people, like the North African Imazighen groups, worshipped two celestial divinities, the sun and the moon, and sacred natural places such as particular mountains, rocks, and caves. Their religion revolved around the need for rainwater, on which the pasture land and crops, and therefore the food for Indigenous people and their livestock, depended. Religious offices were usually carried out by men, although in Gran Canaria and Fuerteventura, these duties were performed by women. Some Indigenous sites have been associated with this cult, such as the cave paintings in Gran Canaria whose interiors display painted geometric motifs, as it is the case of the Cave of Galdar (Tejera Gaspar et al. 2011); the cup and groove sites, consisting of small spherical depressions carved into the rock and linked by man-made channels which are related to the spilling of

liquids (libations); and the sacrificial altars, built in stone and varying in shape although mainly circular, used to burn animals sacrificed as offerings to the gods (Mederos Martín and Escribano Cobo 2002).

The world of death was also related to cultural practices. In the Canary Islands, burial sites are one of the most common finds, although they have been plundered continuously since the eighteenth century. The Indigenous Canarians believed that life continued in another form after death and therefore supplied the corpse with provisions (ceramics, food, awls, beads, rush bags, etc.). They laid the bodies to rest by placing them on beds of stone, vegetation, animal skins, etc. to avoid physical contact with the earth. The most common method of laying out corpses was to place them supine inside natural caves or shelters. In Gran Canaria, they were also placed in tombs (tumuli) or in excavated caves (Arco Aguilar 1992–1993).

Indigenous funeral rituals also included mummification, which was reserved for members of the "nobility" (as a prestige practice) and has been documented primarily in Tenerife and Gran Canaria. In this sense, and according to Abreu Galindo (1602), in the isle of Gran Canaria, nobles and gentry were mummified and then deposited in burial caves. Also, as Arco Aguilar (1992–1993) has argued, the mummified remains studied in the Canary Islands present a size above average and an important level of leptosomia, and they lived longer. These, in fact, are the main biological characteristics of the upper social strata. It is also relevant in the following aspect: mummification is represented by a small percentage compared to non-mummification, and this is indicative of the existence of social differences expressed at the time of burial.

Further evidence of the North African origins of the Indigenous Canary Island populations can be seen in the rock engravings, featuring a script classified as Libyco-Berber which shows clear affinities with scripts recorded in Libya and Algeria (Tejera Gaspar et al. 2011). Moreover, from a genetic point of view, the closest counterparts to 55% of the descendants of the Indigenous populations are found in the Maghreb (Fregel et al. 2009).

Regarding the early colonization of the islands, we are still far from being able to form a final opinion on the situation regarding the Archipelago as a whole, since the extent of the research differs widely from island to island. The present-day situation is unpromising since, although research in recent decades has consolidated the Canarian-African relationship, it is clear that there is still no consensus in terms of origins (How did the islands become populated and colonized? How did the first settlers arrive?). Nevertheless, an examination of the Libyco-Berber inscriptions and radiocarbon dates available from some sites on the islands indicate that the Canary Islands were divided into two geographically overlapping areas of Amazigh influence in different times:

(a) An archaic Amazigh culture in the sixth century BC, including El Hierro, Tenerife, Gran Canaria, La Palma, and La Gomera
(b) A Romanized Amazigh culture dating from the time of Augustus and Juba II, including Lanzarote, Fuerteventura, Gran Canaria, El Hierro, and Tenerife (Farrujia et al. 2010).

On the basis of current research, it is possible to refer to the existence of relations between some islands during the Indigenous period (Tenerife-La Gomera or Lanzarote-Fuerteventura-Gran Canaria), since certain aspects of the material culture would appear to indicate this. However, some cultural features in certain islands are not found in others since, despite the fact that they share the same base, the Indigenous island cultures developed in isolation, with very little contact with the exterior. Given this, the poor quality of the ceramics, except in the case of Gran Canaria, leads to the conclusion that later contributions were rare, indicating cultural isolation until the time when the islands were rediscovered and conquered by the Europeans in the fourteenth century (Tejera Gaspar 2006).

The entire Indigenous culture, which had existed in the Canary Islands since the beginning of the first millennium BC, began to disappear irreversibly following the conquest and colonization of the Archipelago which began in the Late Middle Ages. It should be noted that the Indigenous Canarian culture can only be explained by a continental-African ethnogenesis which is inseparable from the culture of certain ethnic Amazigh groups that lived approximately 2000 years ago. The culture developed in the Canarian Archipelago by Imazighen societies was clearly influenced by insular isolation and adaptation to the island environment under conditions which meant that they were virtually cut off from contact with the African continent and other ethnic Amazigh groups. This has made the Indigenous archaeology of the Canary Islands an extraordinary, marginal, and almost unclassifiable historical example of Amazigh or (North) African culture. In other words, the Indigenous Canarian universe was unarguably Amazigh, although from the point of view of "positive culture," it is a unique case and an extraordinary product of involution (due to isolation) and adaptation to an island environment. The archaeological evidence and findings (ceramics, rock inscriptions, etc.) and anthropological/genetical type (DNA) are indisputable. However, there are many gaps in our understanding of the circumstances in which the first settlers arrived in the Canary Islands. We still do not know how or why the North African Amazigh landed in the Canary Islands in the first millennium BC, although the early colonization of the islands has recently been related to Phoenician-Punic influence in the Atlantic (Farrujia 2014; Arco et al. 2017).

As a result of the rediscovery, conquest, and colonization of the Canary Islands, the legacy of the individual communities that inhabited the different islands in the Archipelago up to the time of the European colonization began to disappear irreversibly as a direct result of the gradual disappearance of the Indigenous Canarian societies. The main factors which explain this ethnocide are capture and sale of Canarian Indigenous peoples as slaves, in the Mediterranean markets; their massacre in the battles, during the conquest; and the "new" diseases introduced by the conquerors, such as the so-called modorra (drowsiness).

In the case of the Canary Islands, unlike the situation in the American continent or in Australia, there is no historical continuity between the Indigenous, pre-colonial, and postcolonial societies, since the conquest and subsequent colonization of the Canary Islands by the Crown of Castile led to the gradual physical destruction of almost the entire Indigenous society. In fact, the Canarian economy became characterized essentially by a model based on agricultural development, which, in turn, formed part of the Atlantic and international economy. This led to the development of a dependent and peripheral economy from the beginning of the sixteenth century and a colonial society composed of a ruling group (the aristocracy, clergy, and merchants, i.e., those who held political positions and controlled the economy) and the majority whom they ruled (laborers, those marginalized for religious reasons, and slaves, including the Canarian Indigenous people) (Macías Hernández 2010).

In the case of the Canary Islands therefore, the concept of "Indigenous" implies clear temporal connotations: it refers to the populations present on the islands since the time of the first settlements in the Archipelago (first millennium BC) until its rediscovery in the fourteenth century by Europeans. In fact, at the end of the seventeenth century, as a consequence of the gradual disappearance of the Indigenous Canarian people and their culture, their legacy began to be viewed from a more archaeological than ethnohistorical perspective. Earlier, in the fifteenth century, Indigenous Canarian populations were still thriving and, since they were not fossils, were not considered from a prescientific "archaeological" perspective (Farrujia 2014).

The rediscovery of the Canary Islands by the Europeans therefore led to the gradual disappearance of the Indigenous settlements; the elimination of material items from the Indigenous culture;

the appropriation of Indigenous areas, which were occupied by the new settlers and by the emerging colonial society; and the imposition of ways of life and systems of social organization and production governed by a western-style world view, values, and regulatory mechanisms that were alien to the Indigenous Canarian world. Over time, the arrival in the Archipelago of an imperialist archaeology, developed during the nineteenth century and a good part of the twentieth century, would help perpetuate the western European interpretation of the Indigenous Canarian past (Farrujia 2005). This scenario clearly contrasts with the North African context, in which the Imazighen, the Indigenous populations of the area, have maintained a constant presence since ancient times (Tilmatine 2008).

The imperialist archaeology in the Canary Islands involved the creation of specific versions of the past history of the Archipelago, all of which are completely different from each other and sometimes totally contradictory, while all tending to justify the social order established in the particular period in which they are produced. After the origins of archaeology in the Canary Islands (1868), and the development of the evolutionist theories, the Indigenous Canarian population was linked to European, specifically French, prehistory. According to Canarian researchers, who studied in France, the Canarian Indigenous people were the descendants of the Celts. From the racial point of view, the Indigenous skulls documented in the Canary Islands were related with the Cro-Magnon race (Farrujia 2014). Cro-Magnon race contributed toward defending French imperialist interests in Africa and the Canary Islands. Reflecting the ethnocentric world view of the time, the expansion of the Cro-Magnon race beyond French territory implied that all the areas occupied by the said Quaternary race would have been populated in ancient times by the ancestors of the Gallic nation. Also, in applying external criteria to the Canary Islands, Indigenous Canarian cultures were treated as if they shared the same evolutionary development as other parts of Europe. In this sense, the cultural evolutionist models simplified Indigenous Canarian societies, as they did to other past societies (Johnson 2010).

Later on, during Franco's dictatorship, the "Indigenous Canarian of European origins" from the end of the nineteenth century became the "Indigenous Canarian of Hispanic origins" with Ibero-Saharan and Ibero-Mauritanian roots during the Franco period. The relationship established between these substratums and the Spanish Sahara enabled to endorse the nationalist politics of the Franco regime since the first settlers in the Iberian Peninsula, the Canary Islands, and the Spanish colony in Africa would have shared the

same racial and cultural roots in ancient times (Farrujia 2014).

Parallel to this, archaeological heritage management underwent certain changes that nevertheless failed to improve the organization, understanding, protection, and dissemination of Indigenous heritage. The nineteenth-century private initiatives, represented by museums and offices run by bourgeois Canarian intellectuals, were replaced in the twentieth century by the intervention of the Franco government, involving a centralized management, the development of fieldwork, a greater number of

excavations, and the reinforcement of a colonial discourse. Canarian archaeological evidence was analyzed on the basis of this colonialist discourse, and this knowledge was essentially disseminated via the museums. The mummies and Indigenous artifacts (basically ceramics and lithic and bone tools) displayed in glass cases and interpreted from this point of view helped reinforce a simplistic, "prehistoric" reading of Indigenous Canarian societies among the general public. In other words, the Spanish government imposed its particular vision of heritage, set up an institutional framework, and organized conservation practices in the Canary Islands. An unequal power relationship was therefore the starting point for any consideration of the Canarian heritage on the part of the Franco regime. The archaeology of the Canary Islands was perceived through the "filter" of the knowledge produced by the "new colonizers" (Farrujia 2014).

Nowadays, the archaeology of the Canary Islands shares three of the most common characteristics of social histories of archaeology worldwide, as defined by authors such as Hodder (2001), Trigger (2006), and Lozny (2011): (a) a culture-history approach as the key methodology and basis for locally generated theories (with a

strong nationalistic flavor), (b) the use of archaeology for political (nationalistic) goals, and (c) a tendency to relate archaeological research topics to existing political conditions and demands. In this sense, the European colonial discourse that influenced archaeology in other Indigenous contexts (Australia, Canada, Africa, etc.) is also evident in the Canary Islands. As Ireland (2010) has pointed out, Indigenous and non-Indigenous communities are all engaged in the active "use" of the colonial archaeological heritage as much as any other forms of tangible or intangible heritage.

The social actors involved in Canarian archaeology are Spanish. It may be said that we now have new, postmodern empires without colonies, endowed with their own knowledge-power strategies. In this sense, according to Ireland (2010), the role of heritage has been closely linked to the construction and reinforcement of national and ethnic identities and, in the postcolonial world, to projects which still legitimize colonial occupation. The Canary Islands is not a Spanish colony but one of the autonomous communities that make up the country. At the same time, however,

Canarian Indigenous People, Fig. 9 Canarian Indigenous mummy from Tenerife (Archaeological Museum of Tenerife)

it is a geographical area politically controlled by a distant country, a vestige of a past empire, a national territory next to the African continent. In other words, they are an overseas territory like the French DOM (Guadeloupe, Guyana, Martinique, and Reunion) and are considered an outermost region (OMR) by the European Union. The actual geostrategic location of the Canarian Archipelago in the Atlantic has helped to historically reinforce the concept of the islands as a Spanish overseas possession and a strategic enclave in relation to the neighboring continent of Africa. These factors and the almost total lack of renewal of theory within Canarian archaeology help to explain, to a great extent, why the colonial discourse still lives on archaeology in the Canary Islands (Figs. 1, 2, 3, 4, 5, 6, 7, 8, and 9).

Capdeville, Augusto

Benjamín Ballester Riesco[1] and
Alexander San Francisco Araya[2]
[1]UMR 7041 ArScAN, Équipe Ethnologie Préhistorique, Université Paris 1 Panthéon Sorbonne, Paris, France
[2]Museo Augusto Capdeville Rojas de Taltal Associated Research, Taltal, Chile

Basic Biographical Information

Augusto Capdeville (1864–1932) was a Chilean archaeologist who discovered the archaeological sites of Taltal, in the north of Chile. This launched prehistorians' interest on this zone and contributed to national and international debates on the origins of the American Man.

Augusto Henri Capdeville Rojas was born in Santiago, on August 20, 1864. His father arrived from Avignon to Valparaiso in 1860, where he met Rafaela Rojas, with whom he had two children, Augusto and Ramón, and a very short marriage. At the age of 3, Augusto loses his mother as a result of tuberculosis, so they move to Talca, in the central Southern part of the country, where they form an extended family of ten brothers and sisters with their father's new wife, Clodomira Miranda. By then, his father had become a prominent business man in the tailoring and hat industry, so the family enjoyed a considerably comfortable life (Looser 1932; Mostny 1964; Núñez 2008).

He completed his studies in Humanities in the Lyceum of Talca and later in the National Institute of Santiago, where he graduated in 1883. Between 1884 and 1885, he studied Law and Medicine at the same time, a project he had to abandon after his father's death and lack of economic support. That is why he had to work as Chief of the Bulletin and then Archivist in the Ministry of Industries and Public Works of Chile; there he meets the President of the country, José Manuel Balmaceda. In 1895, he was transferred to Constitución seaport with the position of Warehouse Guard of the same ministry, where he wrote his first publication (Capdeville 1893).

In 1897, he is transferred to the saltpeter port of Taltal, even though he had asked to be sent to Chañaral, the nearest town to the South. There, he will stay for more than 27 years, together with his wife, Matilde Celis, with whom he has a big family. In Taltal, he starts working as a saltpeter weigher, then Customs Mayor, and finally becomes Chief of Security, a post he keeps till the rest of his stay at the port.

Even with the limited salary of a civil servant and being in charge of seven children, Capdeville devoted a large part of his income to the purchase of books and scientific journals, eventually setting up a huge library specialized in American archaeology and ethnology. Later he concentrates on his own studies and explorations: the first of his archaeological discoveries in Taltal is carried out in September 18, 1914; those go on ceaselessly for almost 10 years (Latcham 1939).

Capdeville collected surface material and excavated about 60 archaeological sites in Taltal, between Caleta Agua Dulce in the North and Caleta Esmeralda in the South, an extension of more than 190 km of coastline along the Atacama Desert coast. His works, with highly detailed field records and highly detailed and subtle drawings, showed the pre-Hispanic occupational intensity of this area and the craftsmanship, social, and cultural virtues of its fishermen. He shared his findings through letters with some of the most prestigious archaeologists, anthropologists, and historians of the beginning of the century, such as Max Uhle, who considered himself as his disciple, Aureliano Oyarzún, Carlos Porter, Jose Toribio Medina, Jacinto Jijón and Caamaño, Walter Looser, Ricardo Latcham, Eric Boman, Carlos Ameghino, Salvador Debenedetti, and Ramón Laval (Oyarzún 1916; Uhle 1916; Mostny 1964).

Capdeville, Augusto, Fig. 1 Augusto Capdeville Rojas

In 1916, Capdeville enters the Chilean Society of History and Geography as a member, and in 1920 he became a Corresponding Member of the Ecuadorian Society of Historical Studies. This membership was achieved thanks to Max Uhle, with whom, during these years, he kept a close communication. In addition, it is the same German scholar who encouraged him to publish his first archaeological works in Ecuador's Bulletin of the National Academy of History between 1921 and 1923. In 1924, he leaves Taltal for health problems to settle in San Antonio, a seaport he

Capdeville, Augusto, Fig. 2 Archaeological work in Morro Colorado Site, Taltal

would leave 2 years later after his retirement in Quillota City. He passes away in Viña del Mar, on September 21, 1932.

Augusto Capdeville's works placed the unknown town of Taltal in the map of the world archaeology, as well as the old inhabitants of the Atacama Desert littoral in the history of the South American inhabitants. All this took place, years ahead archaeology was consolidated in scientific societies and universities, during a phase of the founding of Americanist studies and pre-Columbian past concerns. This is the time when a passionate customs officer became a referent among some of the most prestigious scientists, naturalists, and historians devoted to the South Pacific.

Taltal attracted some prominent researchers; they wanted to personally visit these magnificent sites and make their own excavations, such as Max Uhle in 1916, Ricardo Latcham in 1924, or Junius Bird in 1941–1942. Today, almost a century after his explorations and discoveries, he is still the most important and remembered Taltal archaeology scholar, the foundation of later investigations, and the one who has probably best described the past life of the area's inhabitants. These days, the Taltal Museum bears his name and holds part of his archaeological collections and field notebooks, guarding his archive as a legacy (Figs. 1, and 2).

Cape Gelidonya Shipwreck Excavation

Nicolle Hirschfeld
Trinity University, San Antonio, TX, USA

C

Introduction

Sometime in the late thirteenth or early twelfth century BC, a ship carrying a tinker's materials and tools of trade foundered in the straits off Cape Gelidonya (southwestern Turkey). The wreck, discovered by sponge-diver Kemal Aras in 1954, was excavated by George Bass in 1960. This excavation marked a major milestone in the history of the discipline of underwater archaeology, for Bass, an experienced terrestrial archaeologist before he learned to dive, demonstrated that it was possible to excavate and document as carefully and accurately on the seabed as on land. Additionally, Bass' analysis of the artifacts recovered from the seabed challenged scholars of "Mycenaean" trade to widen their frame of reference beyond an Aegean-centric focus to the larger context of the eastern Mediterranean.

Short visits to the site by a survey team in the 1980s and 1990s indicated that there was more to find at the site and provided a clearer picture of the ancient ship's points of impact and final crash. A second season of excavation in 2010 defined the larger area of wreckage and resulted in the recovery of many more items.

The recent discoveries on the seabed and results of increasingly sophisticated scientific analyses (Bass 2013) have and will continue to add nuance and detail to our understanding of the ship, its cargo, its purpose, and its crew. But Bass' original interpretation remains essentially intact: the ship that sank at Cape Gelidonya sometime in the late thirteenth/early twelfth century BC and its crew originated and sailed within the Canaanite/Syrian/Cypriot/southern Anatolian orbit, for the purpose of dealing in copper and tin and recycled bronze.

Definition

The ship carried mostly the ingredients for making new bronze and broken bronze implements intended for recycling. These included approximately 1 ton of copper in the form of 34 flat four-handled "oxhide" (a misnomer) ingots and about 20 smaller discoid "bun" ingots, another quarter-ton of copper ingot fragments, traces of tin ingots, the aforementioned scrap bronze, and items associated with bronze-working (sprue, a swage block, an anvil, a whetstone, and stone hammers and polishers). Bass concluded that the ship belonged to a tinker – a metal smith who, as he travels, fixes what he can and collects the rest to be dealt with later (Bass 1967, 163–164).

Lead isotope analyses of the ingots indicate that they were made from ore mined in northeastern Cyprus (Stos 2009), and typology and petrographic analyses of the ship's stone anchor and items being used by the crew or their personal possessions point to Cyprus and the Levant (Bass 2010, 802). The ship's orbit was confined to the coasts of southern Anatolia and Cyprus, and those on board came from the Near East (on the basis of their personal belongings and items of shipboard use, Bass 2010, 800–801).

Historical Background

There is the history of the discipline. The 1960 expedition was the first to excavate an ancient shipwreck in its entirety on the seabed. It was also the first time that a trained archaeologist participated as director *and* diver and thus had firsthand experience of the seabed situation. At a time when the only means of communicating about what had been found on the seafloor were discussions after a dive, drawings, or film that needed developing (i.e., before the advent of the easy and immediate availability of digital images or the extensive information rendered by 3D imaging), on-site familiarity was crucial to planning excavation tactics and to accurately understand and interpret a wreck site.

And there is the ancient historical background. When Bass went to Cape Gelidonya, it was generally believed that Mycenaeans held a monopoly on maritime commerce in the Eastern Mediterranean. This belief was based on the wide distribution of Mycenaean pottery throughout the Near East, including Cyprus (references in Bass 1967, 165–166 footnotes 16, 41). The shipwreck, however, preserved evidence for the active role of peoples from the eastern Mediterranean in the metal trade. The most compelling evidence for the identity of those on board is the three sets of stone pan-balance weights (ca. 60 total), which were based on Near Eastern standards (albeit carried in multiples that allow easy conversion to an Aegean standard, Pulak 1996, 255–285). Anthropologists have shown that merchants typically travel with their own sets of weights, with which they are familiar, and use them to convert to the weight standards of the lands in which they deal (Pulak 1996, 280–281; Monroe 2009, 39–56, 101). Furthermore, all the artifacts that may have been used on board or belonged to the ship's crew are Syrian or Cypriot in origin: two stone mortars, a terracotta oil lamp, a razor, the stone hammers, several Syro-Palestinian imitations of Egyptian scarabs, and a merchant's cylinder seal, probably an heirloom, carved centuries earlier in north Syria (Bass 1967, 164; 2010, 800–801). These indicators of people other than Mycenaeans on board the ship led Bass to look again at the Late Bronze Age metal trade as portrayed in Egyptian tomb paintings. Here he found confirmation of what he had found on the shipwreck: contemporary Egyptians associated copper and tin ingots with Syrians, not with Mycenaeans (Bass 1967, 62–67, 74). This turned the traditional theory on its head: the Mycenaean pottery found in quantity throughout Cyprus, the Levant, and Egypt, Bass argued, was best understood as return trade, brought back from the Aegean by people from the Near East in exchange for raw materials such as Cypriot copper (Bass 1967, 165–166).

Key Issues/Current Debates

Bass (1991) lays out the criticisms to his 1967 publication of the 1960 excavations and his rejoinders. First there is the "nationality" of the

ship. Bass' main point in 1967 was that the ship and crew were not Mycenaean, as prevailing scholarly tradition held at the time, but from the Near East; subsequently he refined the locality of likely origin to Cyprus. By dint of persistence and a measure of good fortune, two decades later he found proof that would silence any critics who still insisted on the "Mycenaean monopoly" paradigm. The excavation of the Uluburun shipwreck (1984–1994) provided incontrovertible evidence of an extensive trade in raw materials from the Near East to the Aegean, its cargo a physical example of the shipping ventures attested in the archives of the Late Bronze Age palatial centers at el-Amarna, Ugarit, and Bogazköy (Pulak 2008). The ship that sank at Cape Gelidonya, so different in scale and scope and kind from the Uluburun shipwreck, operated in a sphere of activity not likely to be attested in the records of royal exchange. The general theoretical question, whether it is even possible to define nationalities or assign home ports to ships wrecked in antiquity, remains a point of contention (e.g., Bachhuber 2006, 346, 351–355). But in the particular case of the Cape Gelidonya shipwreck, there is no reason to suggest affiliations beyond the Near East.

In 1967, Bass had to rely primarily on images in Egyptian tombs as evidence for Near Eastern participants in the Late Bronze Age metal trade. Those arguments are now bolstered by scientific analytical techniques: on the basis of lead isotope analysis, Stos (2009) has pinpointed the Solea region of Cyprus as the origin of the copper cargo.

Bass has consistently dated the wreck to the late thirteenth or very early twelfth century. Arguments for a later date in the twelfth century have gradually lost adherents as objects (e.g., scarabs) found in 1960 are re-evaluated in the light of new comparanda (Brandl 2003) or recent discoveries [e.g., transport stirrup jars on the wreck site (Bass and Hirschfeld 2013, 100), an ingot mold at Ras Ibn Hani (Lagarce et al. 1983, 277–290)] add weight to the earlier dating. It is possible that the current study of the assemblage of all the artifacts recovered from the wreck site, 1960–2010, may add something substantial to the discussion.

International Perspectives

Until Jacques Cousteau and Émile Gagnan's invention of self-contained underwater breathing apparatus at the end of World War II, the underwater world had been the exclusive realm of the few burly teams of salvagers and sponge-divers able to manage the cumbersome apparatus of helmet diving. SCUBA made the sea accessible to anyone who wished to jump in. The clear waters and warm temperatures of the Mediterranean first tempted amateur divers, among them photojournalist Peter Throckmorton. His documentation of the Mycenaean era shipwreck that Aras had first discovered at the southwestern tip of Turkey in 1954 (Throckmorton 1964, 101–110, 118–125) enticed George Bass, a terrestrially trained archaeologist, to learn to dive for the purpose of excavating a shipwreck to the same standards as those practiced on land. It was at Cape Gelidonya in 1960 that the underwater exploration of shipwrecks became a scientific discipline.

Future Directions

There is at present a concerted effort underway to re-evaluate the artifacts raised from the seabed in 1960 in conjunction with documentation of the several hundred additional artifacts recovered during the survey and excavation seasons of the 1980s, 1990s, and 2010 (summarized in Bass and Hirschfeld 2013). Because this cargo represents an assemblage deliberately collected in antiquity, it is fitting now to collate the discoveries of the past half century back into their original whole and study and publish the corpus in its entirety. The corpora of ingot fragments and ceramics listed in the 1967 report need substantive revision in light of the recent discoveries, and there are also significant additions to the collections of bronze objects and pan-balance weights. The results of many analytical studies undertaken subsequent to the original excavation and those currently in progress will also be collected or presented for the first time. In particular, building on the typological studies undertaken in the 1960s and lead isotope analyses of the 1980s, pXRF, ICP-MS,

and metallographic analyses of the copper's composition and its microscopic structure will provide further information about where the smith obtained his copper, the various means of metal production, and how and why it was broken up for circulation.

Introduction

Cape Krusenstern is one of the most extensively documented coastal archaeological sites in the North American Arctic. The site complex is located in northwest Alaska on the western shore of the Chukchi Sea and north shore of Kotzebue Sound; the beach ridge system is above the Arctic Circle and at the southeastern tip of Cape Krusenstern National Monument (Fig. 1). The site complex consists of more than 4,000 years of human occupation on a prograding beach ridge system that began forming shortly after sea level stabilized in the region approximately 5,500 years ago. The oldest beach ridges are found near the modern day lagoon, with the ridges successively

Cape Krusenstern Societies, Fig. 1 Location of Cape Krusenstern beach ridge complex in northwest Alaska

younger as one travels seaward (Fig. 2, Table 1). The older human occupation of the site complex is therefore found near Krusenstern lagoon, while the more recent occupations are located closer to the modern shoreline where people still camp, fish, and live today. Before the widespread use of radiocarbon dating, this horizontal stratigraphy played a key role in establishing the regional and Arctic-wide archaeological chronology for the last 4,000+ years. This sequence includes Denbigh (Arctic Small Tool tradition), Choris, the anomalous "Old Whaling" site, Norton-Near Ipiutak, Ipiutak, Western Thule, Kotzebue, and Historic Inupiat, including several type sites of the later archaeological cultures. The beach ridges themselves are a record of past coastal environment and landscape evolution. For these reasons, the Cape Krusenstern beach ridge site complex was designated a National Historic Landmark in 1973. It remains one of the most significant archaeological sites in the North American Arctic.

J. Louis Giddings led the earliest archaeological research at Cape Krusenstern. While carrying out dendrochronological and archaeological fieldwork throughout northwestern Alaska and the Seward Peninsula, Giddings struck upon the idea of "beach ridge archaeology" as a framework for chronologically ordering archaeological deposits as well as studying coastal formation processes and sea level change (Giddings and Anderson 1986). Giddings' field assistant and interpreter of two seasons, Almond Downey of Noatak, suggested Cape Krusenstern as a possible study site. Giddings' team subsequently worked at Krusenstern from 1958 to 1962. Giddings's student, Douglas Anderson, returned in 1965 to carry out additional excavation and also spent the 1973 season mapping unexcavated features. Several smaller-scale archaeological projects were carried out at the Cape and in the surrounding region in the intervening years (e.g., Anderson 1977; Zimmerman 1981; McClenahan 1993; Young

Cape Krusenstern Societies, Fig. 2 Cape Krusenstern beach ridge complex with archaeological limiting age for each depositional unit

Cape Krusenstern Societies, Table 1 Comparison of new limiting ages for beach occupations to prior age ranges and archaeological cultural designations (Giddings and Anderson 1986; Mason and Ludwig 1990; Mason and Jordan 1993; Darwent and Darwent 2005)

Beach segment (Mason and Jordan 1993)	New limiting date	Prior age range	Archaeological culture
I (VII)	1,045 cal BP	900 cal BP to present	Thule, Kotzebue, Historic Inupiat
II (VI)	1,990 cal BP	1,500–1,000 cal BP	Ipiutak, Birnirk, Thule
III (V)	2,780 cal BP	2,500–2,000 cal BP	Norton/Near Ipiutak
IV (IV/III)	3,215 cal BP	2,900–2,500 cal BP	Choris (including Old Whaling)
V (II/III)	4,068 cal BP	3,500–3,000 cal BP	Denbigh, early Choris
VI (I)	4,238 cal BP	4,200–3,500 cal BP	Early – classic Denbigh

2000; Darwent and Darwent 2005). Various projects (Mason and Ludwig 1990; Mason and Jordan 1993, 2002; Jordan and Mason 1999) expanded on initial work on coastal geological processes by Hopkins (Giddings and Anderson 1986) and furthered the coupled archaeological-paleoenvironmental research agenda initiated by Giddings at the Cape. Linked archaeological, geological, and environmental research continues in the region to this day. Research ongoing in 2012 focuses on study of human-environment interactions, with the broader goal of better understanding how people adapted to and altered their changing Arctic environment in the past (Anderson and Freeburg 2009).

Definition

The beach ridge landscape is characterized by low, undulating ridges that can be divided into geochronological sections in part through differences in beach ridge height, width, and composition; differences in these characteristics across sections reflect changes in the coastal environment over the last 5,000+ years (Mason and

Jordan 1993; Jordan and Mason 1999). The ages of the beach ridge sections are roughly defined based on archaeological dates (Fig. 2, Table 1), but current efforts to geologically date ridge formation are key to refining the local chronology of landscape evolution and coastal paleoenvironmental change. The Cape Krusenstern beach ridges, for the most part comprised of pebble and cobble-size rock rather than sand, were deposited during periods of fair weather and eroded over episodes of extended coastal storminess in the region. Correlated beach ridge complexes around the Chukchi Sea coast form a coastal storminess proxy for the region (Mason and Jordan 1993; Jordan and Mason 1999). Initially, the ridges at Krusenstern formed a series of spits that were connected to the mainland at the north end of the beach ridge complex. Over time, these spits grew eastward and eventually connected with the mainland at the east end of the beach ridge complex; this created the brackish lagoon that today serves as the northern boundary of the site and beach ridge system (James Jordan, personal communication, 2011).

The beach ridge system is punctuated by areas of marsh, tundra ponds, and small lakes (Fig. 2). The development of small ridge systems on the eastern and western ends of the largest lakes suggests that the lakes are fairly stable and are at least several centuries old. The lagoon is drained into Kotzebue Sound by the Tukrok River. A series of small seasonal streams and wetlands bound the eastern end of the beach ridge complex. Because of this diverse environment, past and present people living at the Cape have access to diverse marine, terrestrial, and riverine resources. Archaeological faunal deposits indicate that for at least the last 2,800 years, people here relied mainly on bearded and ringed seals as well as other small ice-associated seals and, to a lesser extent, other marine species such as walrus, beluga, and gray and bowhead whales. It is likely that in the past, as in the present, inhabitants of the Cape used the area for late spring/early summer seal hunting. Fish and bird bone preservation is generally poor, and terrestrial fauna are only minimally represented in archaeological deposits although caribou, musk ox, fox, and hare are present. Although the Cape is within the modern territory of the Western Arctic Caribou Herd, caribou do not typically move over the Cape in large numbers today. Presumably people in the past also relied on the plant resources at the Cape for food and other subsistence needs, although there is little direct evidence of this because of poor organic preservation.

Occupation of the beach ridges spans several significant mid- to late Holocene environmental shifts, specifically the Neoglacial and Little Ice Age (LIA). Periods of sustained storminess marked by beach ridge degradation at Krusenstern and other Chukchi Sea beach ridge systems are known from 3,300 to 1,700 ^{14}C yr BP and from 1,200 to 900 ^{14}C yr BP (Mason and Jordan 1993; Jordan and Mason 1999). The relationship, however, between local storminess, climate, and ice conditions is complex. From various regional paleoclimate proxies, it is apparent that the mid- to late Holocene environment throughout northwest Alaska was cooler and wetter than the early Holocene but also highly variable overall. Variability and, perhaps, unpredictability in environmental conditions increased after 1,500 years ago. A period of significant Neoglacial cooling from 4,000 to 1,000 years ago was followed by a period of warming – perhaps related to broader Medieval Climatic Optimum conditions – between 1,000 and 300 years ago. LIA cooling prevailed across the region between about 300 cal BP and the mid-1800s (see Anderson and Freeburg 2009 for summary).

The archaeological site complex encompasses components of the major Western Arctic archaeological cultures of the mid- to late Holocene: Denbigh, Choris, Norton-Near Ipiutak, Ipiutak, Thule, Kotzebue, and Historic Inupiat (Table 2). The oldest beach ridge sites, linked to the Denbigh complex, are small stone tool scatters and hearth features that represent the earliest evidence of seasonal or short-term coastal occupation in northern Alaska. The size and low density of these older sites at the Cape indicate that for more than 1,000 years, people continued to visit Krusenstern only seasonally; lack of faunal preservation makes it difficult to understand what time of year people visited the coast.

Beginning around 2,800 years ago, there is an increase in the number of sites at the Cape and a change in tool technology. Pottery is added to the toolkit, along with ground slate tools and labrets, and chipped tool styles shift as well; these changes suggest increased interaction across the Bering Strait during this period, known as the Choris culture. At Krusenstern, the small-size and limited archaeological deposits suggest continued seasonal or short-term visits to the beach ridge complex. More substantial contemporaneous sites on the Choris Peninsula and at Wales, however, indicate that after about 2,800 years ago, some people began to live on the coast for longer periods of time, building semisubterranean houses for winter use. These changes in technology, subsistence, and settlement patterns indicate increased reliance on marine resources, although caribou continued to be an important part of the diet as well. The potentially unique Old Whaling site at Cape Krusenstern dates to the Choris period as well. As far as is currently known, Choris is the oldest occupation in NW Alaska with a developed maritime adaptation, though it remains possible that evidence for earlier maritime lifestyles has been lost to rising sea level.

The relationship between Choris and subsequent Norton-Near Ipiutak, Norton, and Ipiutak cultures is unclear. Norton-Near Ipiutak culture may have developed out of Choris culture in northern Alaska around 2,500–2,000 years ago (Giddings and Anderson 1986) and can be considered a Bering Strait/northwest Alaskan variant of the broader Norton cultural tradition that extends across western Alaska. In northern Alaska, the limited evidence suggests that residence patterns shifted from large Choris settlements to isolated winter houses and people seem to have had a varied subsistence base during this period. Across northwest Alaska, there is a dramatic increase in settlement size, subsistence, and social complexity after about 1,500 years ago. This period is also marked by considerable technological and subsistence variability, as well as evidence of increased conflict and interaction. At Krusenstern, there is a marked increase in the number and type of sites at the Cape, with the presence of semisubterranean houses indicating permanent or semipermanent cold season occupation of the coast. The relationship between various chronologically overlapping archaeological cultures from this period including those identified at the Cape (Ipiutak, Birnirk, Thule) is not well understood (Table 2). The Ipiutak period occupation at Cape Krusenstern, dated to between about 2,000 and 1,050 years ago, is one of the largest in the region. More than 20 Ipiutak houses and multiple settlements were identified at the Cape through survey and excavation. Ipiutak archaeological culture is defined by the lack of key elements of earlier Norton-Near Ipiutak and Choris technology such as ground slate, lamps, and pottery and also by a distinct lithic technology and artistic tradition that includes intricately carved

Cape Krusenstern Societies, Table 2 Summary of northwest Alaska and Bering Strait archaeological cultures for the last 4,500 years (see Mason 2009 for additional information). Note the overlapping date ranges

Archaeological culture	Approximate age ranges (cal BP)	Geographic distribution
Denbigh	4,500–2,750	Kotzebue Sound, Brooks Range
Choris	2,750–2,250	Kotzebue Sound, Brooks Range, northern Yukon Territory
Norton (Norton-Near Ipiutak in northwest Alaska)	2,250–1,350	Southern AK Peninsula to Western Canada, unknown in Siberia and Chukotka
Ipiutak	1,750–1,150	Norton Sound to Point Barrow, interior of northwest Alaska and Brooks Range
Birnirk	1,350–750	Eastern and western shores of Chukchi Sea
Thule	1,000/950–550	Bering Strait to Greenland
Arctic Woodland	750–250	Inland areas of northwest Alaska
Kotzebue	550–250	Coastal areas of northwest Alaska

bone, antler, and ivory objects. Elaborate burial traditions indicating the development of social difference are less prevalent at Krusenstern compared to other Ipiutak settlements (e.g., Point Hope).

The Birnirk cultural component at Krusenstern is small, limited to two settlements, and lacks many characteristic Birnirk artifacts found at the type site near Barrow. This pattern may be due to differences in subsistence at Krusenstern where caribou and seal, rather than whale, were the primarily focus (Giddings and Anderson 1986: 94). It may be more accurate to describe these "Birnirk-like" sites at Krusenstern as part of a larger Neoeskimo archaeological culture that varies somewhat by region; these sites would then be considered older variants of the northwest Alaskan Thule archaeological culture. The size and abundance of Thule settlements at Krusenstern indicate that occupation of the Cape continued to increase during this period. House sizes are larger and differ in composition from prior periods. Beginning around 550 years ago, there was a shift in the settlement patterns at Krusenstern, with smaller and more dispersed settlements replacing the extensive Thule period settlements. The reason for this change across the region is the subject of much debate. Environmental factors, such as changing resource availability, are commonly cited as an explanation; sociopolitical change brought about by greater articulation with international exchange networks is also a possible factor. Over time, settlement and use of the Cape diminished, particularly after direct contact with Russians and Euro-Americans; across northwest Alaska, people became centralized in larger villages and towns. Today, some families still camp seasonally at the Cape, and many visit for shorter periods of time as part of subsistence activities.

Key Issues and Current Debates

The role of environmental change in the origins and migration of Neoeskimo culture is a topic of debate. Neoeskimo culture (approximately 1,450 cal BP to eighteenth century CE) is considered the antecedent to modern Yupik and Inupiat cultures in Alaska and across the Arctic. In the past, it was thought that Neoeskimo populations expanded into the eastern Arctic when climate warmed around 950 cal BP, about 100 years after the initial influx of Neoeskimo people into Alaska. New paleoenvironmental data and archaeological dates now indicate that this was not the case, and archaeologists are currently exploring new explanations for the rapid expansion of Neoeskimo culture across the eastern Arctic perhaps beginning around 700 years ago, 100–200 years later than previously thought. Cape Krusenstern is located north of the Bering Strait region and is part of a greater Beringian region of long-term human interaction and migration. This location, coupled with a long-term and near continuous archaeological and paleoenvironmental record, makes the Cape Krusenstern beach ridges a key research locale for better understanding the factors underlying the development and expansion of Neoeskimo groups across the Arctic. These efforts to better understand how people survived and thrived in past periods of environmental variability are increasingly important in the face of modern environmental change in northern regions.

A key issue in the archaeology of northwest Alaska concerns the origins of fully maritime adaptations, which is usually taken to mean significant dependence on the hunting of sea mammals such as the seals, walrus, and whales that still predominate in Inuit subsistence economies across the Arctic. While dwellers of the Pacific Asian coast south of the Sea of Okhotsk and in western North America south of the Bering Sea developed these adaptations in the early to mid-Holocene, available evidence suggests that maritime adaptations arrived or were innovated only around 3,000 BP by people living on the seasonally frozen subarctic and arctic coasts of the Okhotsk, Bering, and Chukchi Seas. Dumond and Bland (1995) suggest that this may have been a result of the movement of North Pacific Eskaleut marine mammal hunters into the Bering Strait and Chukchi Sea regions (see also Crockford 2008). Following Mason and Ludwig's (1990) reinterpretation of the beach ridge

sequence at Cape Krusenstern, Dumond and Bland suggest that the anomalous "Old Whaling" site at Cape Krusenstern represents this initial expansion. They then suggest that the better represented Choris phase assemblages at Krusenstern and elsewhere are descendants of Old Whaling. This interpretation makes sense of the available evidence, which is very sparse, and provides a hypothesis for continued research at Cape Krusenstern and elsewhere in the Bering and Chukchi Seas.

Another dimension of the question of maritime adaptations concerns the origins and antiquity of whale hunting itself. Despite its name, considerable debate surrounds the significance of the whale bones found at the Old Whaling site (see Ackerman 1998; Darwent and Darwent 2005). Although archaeologists have sought connections between Old Whaling and contemporary or earlier occupations on the Chukchi coast and northern islands of Siberia (Ackerman 1998), the origins of Old Whaling culture at Cape Krusenstern remain unclear. On the basis of the presence of long lance points and whale bones, Giddings and Anderson (1986) argued that the site represents an early manifestation of active whale hunting. Confounding this interpretation is the absence of harpoon technology there and the absence of any evidence of whale hunting for roughly 1,000 years afterward anywhere in the Bering Strait region. Other researchers suggest that the whale bones may have been scavenged from beached carcasses and the points used for hunting smaller sea mammals. If confirmed through additional research, the recent discovery of a 3,000-year-old carving of a whale hunting scene at the *Un'en'en* site on the south coast of the Chukchi Peninsula, in a site reportedly similar to Old Whaling at Cape Krusenstern (Dan Odess, personal communication, 2008), supports Giddings and Anderson's original interpretation of an actively whale hunting culture tracing back to the beginning of the record of committed maritime lifestyles. If and why whaling was then suspended until the emergence of Neoeskimo traditions 2,000 years ago remains a mystery.

Future Directions

Renewed research at Cape Krusenstern has revised the regional paleoenvironmental and archaeological chronology and settlement history established by Giddings and Anderson in the 1950s and 1960s. Ongoing analysis of systematically collected survey data from the Cape indicate that the settlement record from the last 2,000 years is more complex, and more extensive, than previously thought. Future research focused on human-environment interactions during this period will shed light on the question of Neoeskimo origins and migration, as well as the factors behind significant settlement and subsistence changes in the last 500 years. Research directed at testing hypotheses about the origins of whaling, and the development of maritime adaptations in general, would contribute key data to broader debate on these topics. Crucial to future efforts is connecting research at Krusenstern with current work in Russia; joint international research directed at addressing the research questions outlined here would result in a more comprehensive picture of the mid- to late Holocene human-environment record in the Arctic. Less research driven but more emergent is the rapid erosion of parts of the coast line at Krusenstern and across the Arctic, which is quickly destroying significant portions of the coastal archaeological record. This modern coastal erosion threatens to erase the archaeological record at Krusenstern; excavation aimed at mitigating this loss is as important as pursuing other research goals at the Cape.

Capitalism in Archaeological Theory

Randall H. McGuire
Binghamton University, State University of New York, Binghamton, NY, USA

C

Introduction

At the turn of the twenty-first century, discussions of capitalism permeate historical archaeology. Most of these works are by Marxist scholars, but archaeologists have used a variety of other theoretical perspectives to study capitalism. All of these discussions, however, emphasize everyday life and social relations as the keys to understanding capitalism. Archaeologists also live capitalism, and increasingly scholars are calling for an activist archaeology that challenges capitalism.

Definition

No consensus exists on a precise definition of capitalism or on the historical context of its making. This is because capitalism is not a thing that can be isolated, dissected, weighed, and measured. Rather, capitalism is a complex set of dynamic human relationships that are at the same moment economic, social, cultural, and ideological. People experience capitalism differently, depending upon their position in this web of relationships, and these differences in experience motivate people in their struggle to transform society and their positionality. Modern scholars cannot step away from capitalism to objectively view it because they live and work within the relations of capitalism. As an economic system, capitalism entails private ownership of the tools, resources, and raw materials necessary for production (the means of production) for the creation of goods and services to exchange for profit in a market. The social relationships of capitalism necessitate that workers sell their labor power to

the owners of the means of production in order to survive. In the capitalist wage labor relationship, the owners gain profit by paying workers less than the value that they add to the product. Capitalism promotes a subjectivity that leads individuals to see the self as existing before its cultural construction in relations of kin, community, race, belief, gender, or sexuality. When individuals use the market to distinguish themselves from others, capitalism validates the self. Capitalist ideologies present the autonomous self as human nature and the economic and social relationships of capitalism as either universal or inevitable. Archaeological studies have focused on the social, cultural, and ideological relations of capitalism.

Capitalism transformed labor from a self-affirming, community-building activity that was the source of property rights to a commodity sold in a labor market. This relationship defines social roles. Workers lack access to the means of production and must sell their labor power in the market. Capitalists control the means of production and buy labor power in the market. The capitalist owns the labor process and can sell the products to make profit. On the other hand, workers can only sell their creative energy and their liberty for a given period and are alienated from their own labor as well as its products. Thus, capitalism bases ownership rights to newly created value on ownership of the tools and raw materials used in the production of value, not the labor used to create value.

Alienation refers to the separation of aspects of the human condition that naturally belongs together or to antagonism between aspects that are properly in harmony. Workers lose control of the products of their labor. Capitalist workers do not determine the design, the manner of production, or the disposition of the objects that they create with their hands and minds. Capitalism alienates workers from the act of producing. Deskilling breaks the work down into a series of mindless and repetitive tasks (imagine an assembly line), and mechanization requires workers to serve machines rather than machines to serve people. Capitalism alienates workers from themselves. They become replaceable cogs in an abstract machine instead of human beings capable of defining their own value through direct, purposeful activity. Finally, capitalism alienates workers from other workers by reducing labor to a commodity instead of a social relationship between people involved in a common effort for survival or betterment. The competitive labor market serves to reduce labor costs and increase profits. Workers must compete with each other to sell their labor and to survive. Alienation "frees" individual workers from the social relations of kin, guild, union, or community to act in their own self-interest. This subjectivity of individualism treats relationships between people as if they were interchangeable, modular, and reproducible and fetishizes these relationships in things.

The labor market, the alienation of workers, and the concomitant rationality of capitalism enhance commodity fetishism. Commodity fetishism expresses, mediates, and transforms social relationships between people into objectified relationships between things. Commodities are things produced mainly for exchange. In production, workers make objects. However, capitalist production breaks down production into a chain of many steps so that the workers no longer recognize the input of their own labor. Instead, the finished thing turns into a mystical entity with a monetary market value, as if that latter value was no longer due to the workers' own labor. In capitalism, individuals must enter into the market to procure the things necessary for life. In the market, their only connection with other individuals may be limited to the economic transaction. In capitalist production and exchange, commodities and money express, negotiate, and meditate social relations so that things may come to dominate people. Commodity fetishism prods individuals to use the market and commodities to construct their identities of self.

Capitalist ideologies represent individualism as human nature and deny the historic construction of the economic and social relationships of capitalism in at least two ways. First, ideology naturalizes the culture by making capitalist cultural and historical values, attitudes, and beliefs seem entirely "natural," "normal," self-evident, timeless, and obvious "common sense" – and thus objective and "true" reflections of "the way

things must be." Second, ideology obscures masks or denies the inequalities and exploitation inherent in individualism and capitalist relations. Ideologies implicitly and explicitly invest meaning in material culture, and these meanings influence and are influenced by social behavior.

People live capitalism in their everyday lives. A wide variety of social relations affect that lived experience including class, race, gender, sexuality, and ethnicity. In this experience, people have embraced, negotiated, resisted, and fled capitalism. The realities and reach of capitalism have varied over time. Thus, capitalism has never been unchallenged or totally successful in reducing the social to the individual or every aspect of lived experience to a commodity. Scholars who confront capitalism find lessons for struggle and the means to engage capitalism in this contested experience.

Historical Background

Much about the history of capitalism is contested. Capitalist ideology claims that capitalism does not have a history but rather is an expression of human nature or the expansion of age-old practices of antiquity. Challengers to this ideology write the history of capitalism to show that it has a history, that this history was not inevitable or predestined, and that capitalism springs from a specific historical context. These critical scholars disagree on the epoch of capitalism's origins and on the historical processes that created capitalism. They can agree on two things concerning the history of capitalism. It is a phenomenon of the modern era (post-CE 1500), and it is the dominant form of social relations in the West and probably the world today.

At the broadest level, the debate over capitalism's origins breaks down into three positions (Appleby 2010). Exchange theorists link the origins of capitalism to the early sixteenth-century development of merchant capitalism, based on exchanges for profit, in a global market (Wallerstein 1974). Production theorists argue that the Industrial Revolution at the end of the eighteenth century establishes wage labor as the dominant social relationship of the European economy and marks the beginnings of capitalism (Wolf 1982: 296–298). More recently, these discussions have shifted to debates opposing theories that find capitalism's origin in European agrarian relationships to more global perspectives (Wood 2002).

Merchants profit results from buying goods in a location where they are common and then transporting them and selling them in a location where they are rare. As such, merchant profit has existed far back into antiquity. Exchange theorists argue that technological advances in late medieval/early modern Dutch and English agriculture increased production and freed more people and resources for trade. These agricultural advances coupled with the looting of the indigenous civilizations of the Western Hemisphere built up capital for investment in Europe. Unlike the merchants of antiquity who traded for themselves, Dutch and English merchants invested capital in the first joint-stock companies, such as the Dutch East India Company. These companies traded in exotic goods, enslaved humans, and increasingly in raw materials such as beaver pelts to make felt, deer hides, sugar, and cotton. The profits from these exchanges provided the capital necessary for industrial production and mass wage labor. By second half of the eighteenth century, merchant profit became linked to production and the extraction of profit via wage labor. Merchants brought raw materials from around the globe to Europe where waged workers converted them into finished goods, most of which merchants then sold abroad to meet the needs of the primary producers of the raw materials.

Production theorists find the beginnings of capitalism in the mass expansion of wage labor during the eighteenth century and the rise of industrial capitalism. The British "enclosure movement" encouraged this process as large landowners appropriated communal lands and displaced tenets that had grown food crops. Innovation in agricultural technology and the introduction of new crops, principally the potato, allowed fewer farmers to produce more food. Landowners replaced the tenets with sheep that they sheared for wool. Textile production shifted from craft work to factory production to weave greater

quantities of wool into cloth to meet growing demand in a global market. The factory systems of production entailed a complex division of labor between and within production processes and the routinization of work tasks. Increased mechanization, the division of labor and routinization allowed the first capitalists to replace skilled artisans with unskilled, disenfranchised tenets who had been displaced by enclosure and therefore had to work for a wage to survive. This shift to waged labor gave the capitalist more control over the production process and the ability to extract greater profit from that process. This increased production and generation of capital established the global domination of the capitalist mode of production.

The drive for greater profits in industrial capitalism generates economic cycles of 40–60 years in duration. Modern scholars refer to these cycles as Kondratieff Waves, named after the Russian economist Nikolai Kondratieff who defined them in the 1920s. Capitalists can increase profits by reorganizing the work place (which usually involves increasing mechanization and/or cutting wages) and by expanding markets. During the initial A phase of a Kondratieff Wave, the rate of profit increases, and in the second B phase of a Kondratieff Wave, the rate of profit decreases and economic depressions occur. Innovations in production and/or a shift in production to new commodities initiates the A phase of the wave. We can characterize each A phase by the products produced and the markets that it creates. As production swells, competition between capitalist firms increases saturating markets and the demand for the products. This saturation or realization crisis results in declining rate of profits (the B phase of the wave) until innovations in technology or the reorganization of the workplace creates new markets and demands to spur another A wave. Some scholars claim that increased competition over less profit in the B phase leads to major wars. Regional shifts in the centers of capitalism, transformations in the relations of production, and significant changes in markets occur at the transition between the B and A part of the wave.

The maturation of industrial capitalism initiated the first Kondratieff Wave toward the end of the eighteenth century, and the B phase of this wave hit bottom in the 1840s. During this wave, waged factory workers in Europe and, later, the United States produced consumer goods for rural populations in these centers and for primary producers in the rest of the world. These consumer goods included the factory-made ceramics, glass, smoking pipes, and buttons that archaeologists dig up, but the most important was cotton. Peasants in India and enslaved Africans in the southern United States grew cotton that merchants carried to Manchester, England, and Lowell, Massachusetts. Here, waged workers wove that cotton into cloth. These workers drank tea grown by Asian peasants and sweetened by sugar produced by enslaved Africans in the Caribbean as a stimulant that allowed them to stand longer at their looms. Capitalists sold the cloth primarily to the rural peasants and yeoman farmers of Europe and the United States and clothe the Asian peasants and enslaved Africans who produced the cotton, tea, and sugar. Thus, a small minority of the world's workers labored in capitalist relations of production (wage labor), but their production called into being and maintained noncapitalist relations of rural production and racialized slavery elsewhere in the world. Commonly capitalist seeks to maintain the growth of the A phase by opening new markets. Thus, in the early nineteenth century, the British sponsored and supported the liberation of Spanish America which removed Spanish restrictions on British trade to the region.

Steam power and railroads drove the next Kondratieff Wave that began in the 1840s and continued until the end of the nineteenth century. The expansion of transportation infrastructure (railroads) drove the A phase of this wave. Railroads increased the efficiency of transportation and lowered the cost of goods. Railroad construction also created demand for steel, wood, cloth, and glass to build the tracks and trains. Steam powered the locomotives and also larger factories that employed more waged laborers to produce consumer goods. Increasingly waged laborers took up more of the market for consumable goods in core industrial states, but outside of Europe and North America, the vast majority of people of the world labored in noncapitalist

relations of production. The completion of the railroad net in core states initiated the B phase of the wave. For the United States, this event occurred in 1877, and the immediate decrease in demand plunged the country into a deep depression. In the B phase, capitalists sought new markets and built railroads in South America, Asia, and Africa. In South America, the United States and European powers controlled economies and expanded both wage labor and debt peonage. European powers divided up Asia and Africa into colonies. Significant shifts also occurred between centers. For example, at the transition to the B phase in the mid-1870s, industrial production in the United States exceeded that of Great Britain and Japan industrialized.

During the first half of the twentieth century, the third Kondratieff Wave began, driven by steel production, chemicals, electric motors, and internal combustion engine. In this wave, wage laborers became the majority of workers in the core industrial states of Europe and North America but not in the rest of the world. Much of this production focused on durable goods primarily for consumption by the bourgeois class. In Europe, production for the colonies drove a great deal of the demand. In the United States, production of consumer goods still focused on rural populations with an increase in production of durable goods. At the end of the A phase of this wave, capitalists sought new markets by expanding the production of durable goods for wage laborers. The most famous example of this is Henry Ford who initially produced the Model T automobile for farmers but then shifted the market to industrial workers. This period witnessed the widespread reorganization of the work processed to assembly line production, which allowed capitalists to increase profits but still increase wages. The third wave ends with the Great Depression of the 1930s and World War II. In the B phase of the wave, state communism established itself first in Russia and later in Eastern Europe and China. During World War II, industrial production expanded in Latin America, especially in México and Brazil.

The automobile drove the fifth Kondratieff Wave from World War II to the 1990s. In the core areas, factories produced durable goods for waged laborers. Generally in this wave, capitalists increased profits through mechanization. Increases in wages allowed more workers to buy more stuff, especially durable goods, most notably the automobile. During this wave, the United States was unquestionably the dominant economic and political power in the world. In the B phase, capitalists sought to raise falling profits by lowering wages. They did this by increasingly shifting consumer goods production from the core industrial states to Asia and Latin America. In the A phase of this wave, independence movements swept the colonies of Europe, and during the B phase, communism collapsed in Europe and was transformed into a state capitalism in China.

It is difficult to study and understand a long wave when you are in the midst of it. Several clear shifts have occurred in contemporary capitalism. These would include the following: (1) the rise of information technology and computers which has increased the importance and volume of production of intellectual and creative commodities such as computer programs, entertainment, and apps; (2) capitalists increasing profits principally by lowering wages; (3) deindustrialization of core economies especially in Western Europe, Great Britain, and the United States; (4) production of consumer goods that primarily occurs in Asia (especially China) and Latin America; (5) global advances in communications and transportation that speed up the global processes of capitalism; and (6) the rise of China as capitalist economic power and the establishment of the European Union.

Some scholars and popular pundits argue that we now live in a postindustrial or postcapitalist world. We may be able to speak of Detroit, Michigan, as a postindustrial city or Great Britain as a postindustrial nation, but in no sense is the world postindustrial or postcapitalist. To the contrary, capitalism has intensified and extended its reach further than any other time in history. We live in an era of fast capitalism (Agger 2002).

We still live in a capitalist world where economic processes are based in the ownership of private property and waged labor. Modern capitalism, however, is an accelerated, hyped-up capitalism that holds a more profound sway over the

peoples of the earth than it ever has before. The world is, in fact, more capitalist today than it was when Marx wrote in the middle of the nineteenth century. At that time, private property and waged labor only dominated in Europe. For most of its existence, capitalists increased profits by incorporating noncapitalist regions of the world or by expanding wage labor into new geographic areas. Today, virtually no corner of the world lies outside of capitalism's control. Capitalists now increase profits by speeding up the processes of capitalism and by penetrating all aspects of social life. The globalization of the modern world is neither new nor unique. Capitalism began as a global phenomenon. What has changed is the speed of global capitalism. The rapid expansion of information technologies (including computers, software, satellites, fiber optics, and the Internet) has transformed the global economic landscape. These expansions accelerate capitalism both in terms of speed and reach. Advances in transportation, such as container ships, allow goods to be produced wherever in the world wage rates are lowest. The new information technologies allow technical, clerical, and even professional services to cross the globe seeking the lowest wage. To make a profit, firms must cut wages and overhead. Workers who do not accept less lose their jobs as whole industries hop around the world. The pressures to deliver all goods and services at the least possible cost create hypercompetitiveness. This process erodes worker's rights and benefits and proletarianizes professional occupations including archaeology. Fast capitalism expands by oozing into every nook and cranny of society to create new needs. Powerful capitalists in business, education, and government embrace hypercompetition to make market principles the dominant ethic for all social relations. They evaluate all social relations in terms of costs and benefits and by the bottom line of profit. Their success corrodes socially derived moral frameworks and political programs.

Key Issues

Archaeologists confront many issues in the study of and the living in capitalism. Scholars studied prehistory and ancient civilizations to demonstrate that the relations and ideology of capitalism are not simply human nature or universal. Archaeologists have asked how the temporality of the everyday is enmeshed within the broader developments of the capitalism. In particular, they have examined how people have challenged capitalism in the everyday. Archaeologists have paid particular attention to the development of capitalist ideologies and their manifestation in the material world. Finally, archaeologists work and live within capitalism. Some have examined how our work reinforces or challenges capitalism, and others have examined how capitalism shapes the practice of archaeology.

Archaeologists have demonstrated that capitalist class relations are but one of many different ways in human history that elites have appropriated labor and the products of labor from primary producers. Moreover, these scholars also seek to use a deep understanding of past societies to show that as a historical product, capitalism can be changed. Such studies begin with V. Gordon Childe (1951) who argued that scholars must take sweeping historical views to see past the immediate realities and beliefs of capitalism. Luis Lumbreras (2005) has followed in Childe's footsteps, asking questions about the origins of stratification and writing the history of stratification before capitalism in Latin America. Bruce Trigger (2003) did a comparative study of early civilizations to define similarities and differences with an eye to how such an understanding could better enable us to alter our capitalist world. Robert Chapman (2003) argues that to understand how inequality was created and maintained in the long sweep of human history is the basis for critique and action to transform the complex and unequal world of capitalism.

Numerous researchers have argued that archaeology provides a necessary approach to study the lived experience of capitalism and to subvert the ideological masking of this experience (Orser 1996; Leone and Potter 1999; Matthews 2010). The historical changes in production and the extraction of profit in capitalism are written upon the artifacts and feature that archaeologists study. Archaeologists find these things as the result of their use in daily life. More importantly,

material things are more than just the reflection or outcome of human hands and machines. They express the social relations that are the conditions for their existence. They are both the products of social relations and part of the structure of those relations. Through them, we can study how capitalism transforms and is transformed by daily life. Archaeology also gives us an access to daily life that avoids ideologically loaded written records.

In Great Britain, archaeologists have researched the transition from feudalism to capitalism, while US researchers have looked for the beginnings of industrial capitalism. Matthew Johnson's (1996) *An Archaeology of Capitalism* is the seminal work in this vein. Johnson finds the roots of capitalism in the movement from openness to closure in this landscape. Other archaeologists have excavated in tenant cottages abandoned due to enclosure. For example, Chris Dalglish's (2003) study of rural southern Scotland compares changes within the domestic space of the house with larger transformations of the landscape that were labeled "improvements." Both of these works emphasize the contradictions and conflicts between the domestic and the broader world and in the social relations that exist in each of these contexts. Sarah Tarlow (2007) shows how the archaeology of late eighteenth-century England manifests a widespread and crosscutting ethic of improvement in early capitalism. Thomas Cuddy (2008) examines archaeological sites in the Chesapeake region of Maryland to explore the origin of industrial capitalism in the United States. He charts the stages of production from household manufacturing to larger workshops to mechanized factories.

North American archaeologists have found new insights about rural, Native American and African-American experience by examining them as aspects of capitalism. Mark Grover (2003) studied a rural farmstead in eastern Tennessee that might be facilely dismissed as marginal hillbillies. He shows how the household was economically part of the larger experience of American capitalism. In the history of California, Native Americans often disappear after the missions are closed in 1840. They of course did not but instead became an ethnically distinct part of the California working class. Stephen Silliman (2004) reconstructs the everyday life of indigenous workers and the social relationships of labor that shaped that experience to show how they were a key component in the multiethnic labor force of mid-nineteenth-century California. Paul Mullins (1999) examines how African Americans in twentieth-century Annapolis used consumption to negotiate class and racial identities.

Many archaeologists have looked at capitalism in terms of the challenges and resistance that it engenders. Some of these studies have focused on working-class life, strikes, and how workers subverted the work disciplines of capitalism (Shackel 2009). Archaeologists have also sought to humanize and treat populations as active agents that capitalist ideology demonized. These studies include extensive research on enslaved Africans and indigenous peoples, investigations of urban slums and of prisons, and communities of deportees. Others write alternative histories that challenge capitalism by revealing life ways that existed at the edge of/or beyond capitalism. These life ways include utopian communities, cultural practices such as African-American hoodoo, cooperative housekeeping, and communities of escaped slaves or quilombos (Matthews 2010).

Much contemporary archaeological research work focuses on capitalist ideology. They find material culture to be an active component in the creation and negotiation of ideology. This work starts with Mark Leone's (2005) interpretation of the Georgian Order of the eighteenth-century Anglo world as the ideology of merchant capitalism. Heather Burke (1999) uses a study of the nineteenth-century Australian town of Armidale to explain variation in architectural style through relationships of ideology, capitalism, and identity. James A. Delle (1998) examines a nineteenth-century Jamaican coffee plantation as a cultural, ideological landscape that structures relations of race, gender, and the division of labor. Concerns with ideology have also expanded into broader, archaeological studies of capitalist cultural production.

Archaeology is a product of capitalism and practiced in capitalism. It originated in early nineteenth-century Europe as a practice that served the interest of bourgeois nationalism (Trigger 2006). Scholars have questioned

archaeology's history of advancing imperialist, colonialist, and racist objectives (Hamilakas and Duke 2007). These critics argue that archaeologists need to recognize that the discipline is about living individuals and communities whose lives and heritage suffer from the abuse of capitalist power relationships and to adopt a political ethic for the discipline. Fast capitalism has not been kind to archaeology (McGuire 2008). Fast capitalism attacks the values and social relations that created and sustained archaeology. Hypercompetition leaves slight place for the life of the mind that does not produce profits. The camaraderie and shared purpose of fieldwork do not generate earnings. Fast capitalism undermines the relationships of apprenticeship and mastery and grinds down the community of scholars that draws most people to the craft of archaeology. Capitalists' search for profit transforms archaeological knowledge, heritage, and education into commodities to be produced at the lowest cost for sale in a competitive market.

International Perspectives

Most scholars have viewed capitalism through a Eurocentric lens, as reflected in the historical summary in this entry. More recent analysis has focused more on capitalism as a global phenomenon not fully understandable in terms of its European/US core. Archaeologists have also expanded their studies beyond the core.

The development of dependency theory in the 1970s questioned both capitalist theories of modernization and a Eurocentric perspective on capitalism. Researchers from the Global South including Samir Amin of Egypt, Celso Monteiro Furtado of Brazil, and Raúl Prebisch of Argentina wrote the first drafts of this theory. They challenged the basic tenant of post-World War II modernization theory, to wit, that the Global South was poor because it was underdeveloped. Instead, they argued that the underdevelopment of the Global South was both a cause and a result of the development of capitalism. They noted that during the medieval period, Europe had been the poor backwater and the Islamic world the wealthy metropole. In a similar vein, they observed that México City and Lima, Peru, had been wealthy cities with great buildings and universities when New York and Philadelphia were provincial towns with muddy streets. Dependency theorists argued that the modern periphery of the world economic system (the Global South) became poor because core states coercively integrated the periphery into the European economic system. This integration reduced the periphery to producers of raw materials or served as repositories of cheap labor, and dominant states denied the periphery the opportunity to competitively market their resources. Eighteenth-century India provides an example of this process. Before the British conquest, India produced the greatest quantity of cotton cloth in the world. The British forbade the spinning and weaving of cotton in India and transported Indian cotton to Manchester, where British wage laborers wove it into cloth that British capitalists sold to India. The German-US economist Andre Gunder Frank and the US sociologist Immanuel Wallerstein picked up on these ideas and expanded them into world-systems analysis.

World-systems analysis expands the scope of capitalism and rejects the idea that scholars can understand the origins or the development of capitalism from a perspective of European history. It also calls into question those who see contemporary globalization as a new or unique feature of capitalism. Some authors have criticized this theory as still being top-down and as over emphasizing a functional view of economic relations while ignoring the importance of culture. Eric Wolf (1982) has criticized the approach because it leaves the active, creative force of history in Europe and focuses on how Europe created the periphery. For Wolf, this perspective does not capture the dialectical relationship whereby the periphery also created the core, and it trivializes the cultural diversity of the periphery.

Some archaeologists have expanded their considerations of capitalism beyond the core to the peripheries of the Global South. Many have followed the path of world-systems analysis, while others have focused more on the active and creative role of cultural and economic processes in the Global South. In South Africa, Gavin

Lucas (2006) examines the Dutch East India Company; free settlers and enslaved Africans used material culture to construct identities. He mobilizes archaeological evidence to show how these different groups were enmeshed within racial, sexual, and class ideologies in the broader context of capitalism and colonialism. Sarah Croucher (2011) works in Zanzibar. Here, in the nineteenth century, Omani Arab colonial rulers of the East African Coast established clove plantations that marketed the spice in the global capitalist market.

Future Directions

Archaeologies of capitalism have increasingly focused on the contemporary and political action. Traditionally, archaeologists studying capitalism have sought to better understand capitalism and engage a culture critique of capitalism. Following Bourdieu, archaeologists are increasingly trying to be scholars who help a little bit by providing tools for liberation.

Archaeologists find violence, destruction, and ruination in the contemporary. The authors in Pedro Funari and Andrés Zarankin's (2006) collected volume use archaeology to look at the repression that swept Latin America, particularly in Chile, Argentina, and Brazil, from 1960 to 1980. Alfredo González-Ruibal (2008) invokes a concept of supermodernity that parallels the notion of fast capitalism to examine the outstanding relevance of destruction in our times. Shannon Lee Dawdy (2010) uses the theory of Walter Benjamin to study the spatial and temporal dynamic s of capitalism's creative destruction in post-Katrina, New Orleans.

A major focus of contemporary archaeological practice has been on building public scholarship and activism that disputes capitalism. Barbara Little's (2007) book, *Historical Archaeology: Why the Past Matters*, builds on Marxist critical theory and feminist perspectives to address questions of ethics and public scholarship in capitalism. She encourages archaeologists to ask questions that go against the status quo and take action to make untold histories known. Little argues that the social relevance of historical archaeology lies in social capital, civic renewal, and transformative learning. She shows how historical archaeology is inextricably linked to public education, justice issues, and our collective understanding of the past. My own book, *Archaeology as Political Action* (McGuire 2008), builds a Marxist dialectical theory of praxis to show how archaeologists can use their craft to challenge capitalism. Praxis springs from the realization that people make the social world in their everyday lives and that they can also subvert and transform that world. Praxis entails a complex dialectic between knowing the world, critiquing the world, and taking action in the world. The vast majority of twenty-first-century North American archaeologists continue to do archaeology to learn about ancient pasts even as some of us embrace an archaeological study of the present. Today, however, the study of the past cannot be an escape from the present.

Capitalism: Historical Archaeology

Susan Kepecs
Department of Anthropology, University of Wisconsin-Madison, Madison, WI, USA

Introduction

The development and persistence of capitalism is one of the big questions about the trajectory of humankind, equal in importance to the rise of agriculture and sedentism or the advent of the state. Though the time and place of its beginnings are a matter of debate, capitalism is a relatively recent phenomenon, falling squarely within the epoch of written history. For these reasons, capitalism is an anthropological subject and a historical one, and because it is a materialist scheme bound up in the production of commodities, the archaeological record holds crucial information about the ways in which the capitalist system has played out in peoples' lives. Many researchers, especially those in the capitalist core – the USA and Europe – argue that capitalism is the central subject of historical archaeology (e.g., Johnson 1996: 1–3; Leone and Potter 2003: 19; Matthews 2010; Orser 1996: 71–81). (It is worth noting here that though China today is also a capitalist force,

there is no available Chinese literature on the historical archaeology of capitalism.)

Today there is a burgeoning literature on the historical archaeology of capitalism. Much of this work has been carried out in the USA and Britain or by researchers from these countries who work in the so-called developing world; however, the scope is broadening, and new work from other regions, including Latin America, Scandinavia, and Africa, is beginning to appear (e.g., Leone and Knauf 2015). Nevertheless, beyond the capitalist core, the colonial world system brought into play diverse modes of production – European-imposed tribute, feudal systems, debt peonage, and indigenous practices (Wolf 1982; Stern 1993a, b); introduction of the full-fledged, wage labor-based capitalist mode of production has been variable across time and space and still does not prevail everywhere in the developing world. Thus, as Charles Orser (2010: 114) notes, insisting that capitalism is the true subject of historical archaeology is Eurocentric. For this reason, many historical archaeologists outside the "developed world" have explored a different set of issues rooted in the colonial/postcolonial condition, including domination and resistance and sociocultural identity (Funari et al. 1999).

Since the 1980s, when historical archaeology was in its infancy, two key approaches have dominated the literature in the USA; both, not surprisingly, are forms of neo-Marxism. Critical neo-Marxists (or "critical theorists") are concerned with how the dominant ideology masks social inequalities, how capitalists use this ideology to perpetuate the system, and how workers use it to negotiate the system's demands. World systems researchers "break the crust of Marxism" (Wallerstein 2007: 14) by examining the relations of production beyond the boundaries of the state; they examine local or regional data through the lens of global economic links in order to follow the broad, systemic processes of change that occur as regions integrate into the expanding capitalist world economy or undergo booms and busts that shift their position within the hierarchy of global economic interaction. Since the start of the new millennium, some archaeologists have taken a third approach, classical Marxist dialectical analysis, in which researchers look for the contradictions inherent in the capitalist system – the opposing elements that make up the whole (Orser 1996: 185–187).

Yet studying capitalism is problematic; archaeologists disagree on its definition and on when it began. The critical theorists generally begin with the eighteenth century. It is then, in the USA, that "putting-out" capitalism, in which surplus goods were produced in the household and sold to merchants for resale at profit, began to shift toward capitalist labor relations in the Marxist sense. Two interrelated factors facilitated this change. Laissez-faire capitalism overrode state regulations on trade, allowing merchants increasing wealth and control. Merchants at the top were able to purchase the means of production, and the resulting wealth allowed them to industrialize. The essential condition of industrial capitalism is the abstraction of labor. Labor is separated from the household context. Workers no longer own the means of production; instead, they must sell their labor – the only commodity they still possess – to the capitalists. This break with the past precipitated radical changes in the structures of everyday life, which are the main subject of the critical theorists' investigations.

Yet the central purpose of capitalism is to produce wealth from profits made through the sale of commodities at prices higher than the cost of making them (Matthews 2010: 16), and this kind of economic system has been functioning since well before industrialization. Thus some researchers take the sixteenth century as their point of departure. Though capitalism in this epoch usually did not involve the abstraction of labor (Wolf 1982: 86–87), Orser (1996: 27) lays out a set of intertwined "haunts" that he defines as the true subject of historical archaeology – "Eurocentrism, colonialism, capitalism, and modernity" – all of which are rooted in the age of European expansion.

Orser is not a world systems researcher, per se, but he is interested in the changes the growing capitalist world economy has wrought on disparate communities across the globe (e.g., 1996: 18–21) since the dawn of the sixteenth century. And as investigators directly linked to world systems theory, including historical sociologist Andre Gunder Frank (1979) and cultural

anthropologist Eric Wolf (1982) point out, multiple political-economic systems can participate in the same world system. Thus trade flourished between Europe's petty kingdoms and the Mongolian empire in the thirteenth century (Abu-Lughod 1989), and goods produced under various economic systems in Europe, Asia, and the New World flowed into the Europe-dominated global economy in the sixteenth century. Wallerstein, one of the chief formulators of world systems theory, wrote (1979: 6) that in the sixteenth century "we saw the full development and economic predominance of market trade. This was the system called capitalism. Capitalism and a world economy (that is, a single division of labor but multiple polities and cultures) are obverse sides of the same coin."

A world economy is built on what Annales historian Braudel (1986: II:582) called "the miracle of long-distance exchange" – the wider the circulation net, the more profitable it becomes. Wallerstein's single division of labor is the key characteristic of this widening exchange; with it comes interpenetrating accumulation, in which elites in one polity capture part of the surplus exacted by their counterparts in another (Gills and Frank 1991). Interpenetrating accumulation is systemic – it engages people from multiple social strata, creating a complex political economy that shifts some labor (formerly invested in domestic production) to surplus production for exchange. As more workers are tied up in production for long-distance trade, more surplus in essential domestic goods is needed to meet local and regional demands. Markets arise to distribute goods that supplement domestic economies, and monetarization emerges so that prices for commodities can be fixed.

Interpenetrating accumulation and markets are necessary but not sufficient conditions of incipient capitalism (Braudel 1986: II: 589–594; Blanton 1985) – the crucial factor is the appearance of economic forces unregulated by the state. Strong states control accumulation and dampen competition; under weaker political conditions (such as the petty kingdoms of medieval Europe), merchants can reach the top of the economic ladder, from which they can control surplus production and distribution. In some cases, the conditions for incipient capitalism were in place even before the sixteenth century. Historical sociologist Janet Abu-Lughod (1989) finds them associated with thirteenth-century textile industry in Flanders; Braudel (1986: II: 589–594) argues for their presence more generally in feudal Europe and in late feudal Japan. These studies are based on the written record, though the documents were sifted for material evidence. And there is archaeological evidence of pre-sixteenth-century capitalism in late pre-Hispanic Mesoamerica. Within the late pre-Hispanic Mesoamerican world system (Blanton and Feinman 1984; Smith and Berdan 2003), traders from the Aztec tributary empire exchanged goods with their counterparts from the small, politically decentralized polities of Yucatan, where Kepecs (2003, 2005) finds evidence for incipient capitalist conditions in both the material record and the native *Books of Chilam Balam*. (The *Books of Chilam Balam* are colonial period documents written in Yucatec but in European script, though the literate pre-Hispanic Maya wrote in glyphs. The books, which mixed prophecy and history, were kept throughout the colonial epoch, though they contain sections that clearly refer to the late pre-Hispanic past). What distinguishes incipient capitalism from its modern counterpart is core-periphery hierarchy, which refers to the so-called developed world and the developing world – a phenomenon that emerged as Europe became the core of the global economy in the sixteenth century (Kepecs and Kohl 2003).

Background and Development

The use of the critical neo-Marxist and world systems frameworks in archaeology began in the 1980s. Both appeared in response to processualism, a generalizing, positivist practice aimed at discovering general laws of human behavior (Binford 1968; also see Trigger 1989) that characterized the cutting edge of prehistoric archaeology during the 1970s and early 1980s. Processualism was also, as its name implies, about processes – it developed in response to the cultural-historical explanations of culture change

rooted in early-twentieth-century archaeological practice. The atheoretical culture historians explained change as the result of migration or diffusion, leading to notions such as the one that Mesoamerica's pre-Hispanic pyramids were built by ancient Egyptians. The processualists believed that social formations developed in situ, through similar general processes that could be found worldwide (i.e., population pressure on resources led to increased organizational complexity and sometimes to eventual collapse).

Critical neo-Marxism is one of numerous post-processualist approaches, which were forged in the crucible of European philosophy between the World Wars (Johnson 2006: 126). Post-processualism is a radical departure from processualism because it focuses on historical rather than general processes. Further, post-processualists are concerned with how the investigator, in the present, interprets the past. In this context the critical theorists are activists, engaged in a two-pronged pursuit: they aim "to produce the enlightenment necessary to overcome the coercive social forces that have facilitated the longterm success of capitalism" (Leone et al. 1987: 284) and also to clarify how specific political interests are served by archaeological interpretations made in the present (Leone 2010; Preucel 1995).

World systems theory, a branch of historical sociology, entered pre-Hispanic archaeology when some processualists, unable to explain certain diachronic changes in their archaeological data in regional terms, sought a way to examine macroregional shifts without resorting to simplistic claims of migration or diffusion (e.g., Blanton and Feinman 1984). World systems research is historical, in that its aim is to account for the rise and persistence of capitalism. But like processualism, it also is comparative – observed local or regional patterns are considered in the context of macroregional information and then, through appropriate middle-range assumptions, checked against the model. General world systems characteristics include core/periphery hierarchy, interpenetrating accumulation, and also a number of long- and short-term cycles in which the world economy rises and falls (Frank 1979; Wallerstein 1974; Modelski and Thompson 1996).

Orser (1996: 184–190, 2014: 66–69) calls for a dialectical approach, exhorting historical archaeologists to look for the contradictions inherent in the capitalist system. He notes that contradictions can arise within social units – households, settlements, and societies – but they also occur across the netlike connections of the world system, and thus the dialectical approach must be multiscalar. It also must be diachronic, because the social relations that exist in any given period are the result of earlier processes. Dialectical scholarship is inherently activist, using archaeological information to help clarify dynamic tensions in the material histories of present and past, bosses and labor, and race and class.

Critical Neo-Marxist Studies

Most investigations to date are informed by the critical neo-Marxist perspective. The roots of this research are found in James Deetz' *In Small Things Forgotten: The Archaeology of Early American Life* (1977). Deetz examined various material categories – houses, gravestones, foodways (faunal remains), ceramics, cutlery, and furniture – and found a consistent pattern: between 1760 and 1800, a profound shift in American material culture occurred. House forms, once vernacular, with corporately used, multipurpose space, gave way to formal, symmetrical structures with specialized spaces, based on English interpretation of Renaissance style. The Georgian style quickly was adopted in urban New England. With this transition came additional changes that underscored increasing social isolation. The colonists once ate from shared wooden vessels, called trenchers; in the Georgian epoch, individual place settings appeared. Foodways also shifted; ubiquitous stews gave way to meals in which meats, vegetables, and carbohydrates were served separately, as they commonly are today.

Deetz does not name capitalism as the specific cause of this new worldview, but Leone (1999: 196–198), taking the next step, spelled out the Marxist conditions of capitalism in detail. What Deetz had observed was the shift from corporate lifeways based largely on household or community-based production to the spatially and psychologically segregated lifeways created by

the isolation of individuals who compete to operate the means of production owned by capitalist bosses. People in the capitalist workforce are treated as interchangeable modules; when it originated, this practice gave rise to a cognitive pattern in which the individual, rather than the family or community, is the social actor. Moreover, while Deetz assumed uniformity in the transition that swept the American colonies in the latter half of the eighteenth century, Leone assumed that individuals would participate differently in the developing system.

For Leone and other critical neo-Marxists, the archaeological key is to understand commodities as highly symbolic social things that play an active role in capitalist society. To do this, the researcher must grasp the ideology behind the material record, a task accomplished in part by working backward from an acute consciousness of the researcher's own views. Through this process it is possible to understand how the switch from trenchers to ceramic place settings both reflects and reinforces the separation of individuals and their labor from the household context – a dual phenomenon that is imposed by the wage labor system and facilitates the capitalist mode of production.

Leone has applied this approach to a variety of cases including the William Paca Garden in Annapolis, Maryland (e.g., 2010: 67–84), a formal, planned landscape originally created in the 1760s and reconstructed in the 1970s. Paca, a signer of the Declaration of Independence, was both a supporter of liberty and a slave owner – an inherent conflict that provides another example of increasing social segmentation. Paca's garden, set beside his Georgian mansion, was laid out in a series of segmented spaces and emphasized Renaissance principles of perspective, creating an illusion of distance. Leone argues that formal gardens of this sort used natural elements – plants and trees – and references to the past (Renaissance references to classical antiquity) to "naturalize" the social order of the present in which they were built and thereby (Leone and Knauf 2015: 13) to naturalize the exploitation of labor that is a hallmark of capitalism.

Critical theorists also consider the ways in which disenfranchised individuals or groups – women, African-Americans, and religious offshoots – managed to resist the dominant ideology while still functioning within the capitalist system. For example, in his synthetic volume on the archaeology of American capitalism, Matthews (2010: 184–187) summarizes multiple studies of colonoware – simple, low-fired pots manufactured locally by slaves and often found in rivers near large plantations. Many of these pots bear African symbols, including a cross or "X" that is the basis of a cosmogram used by the Bakongo, a Bantu group from the West African coast. The Bakongo cosmograms represent crossing over, from living to dead or material to spiritual. Thus the presence of colonoware in plantation rivers may represent a ritual designed to transcend the boundary between land and water. Most researchers, Matthews notes, interpret the use of Bakongo symbolism by African slaves as an affirmation of their spiritual heritage; yet this reasoning fails to take the American context in which these pots are found into account. In addition to their role in African rituals of transcendence, Matthews maintains, these vessels crossed the line between their potential capitalist function – that is, market value – and their spiritual function. By imbuing their pots with ritual purpose, the slaves on American plantations symbolically challenged the capitalist order.

More recently, Leone and Pruitt (2015), dissatisfied with approaching the ways in which capitalists manipulated space or how disenfranchised groups resisted as separate phenomena, have turned their attention to how slaves and landowners, as two parts of the whole population at Wye House, a plantation house in Talbot County, Maryland – together by proximity if not volition – created a new gardening culture in the early nineteenth century. Pollen data recovered from a greenhouse on the plantation suggest that the plantation owners, interested in scientific gardening, used certain flowers that open and close at set times of day to prompt servants in their work of running the plantation properly; thus there would have been a certain notion of natural time shared among plantation bosses and African-American slaves. Further, pollen data indicate that the slaves, whose knowledge of ethnobotany was

adapted for the New World through contact with Native Americans, gardened alongside the British. Both groups were greatly skilled gardeners; because of proximity, their medicinal and spiritual uses of certain plants merged to some degree.

In Mesoamerica, anthropological historical archaeologists have taken a somewhat similar though more diachronic approach, considering how indigenous groups recombine their beliefs and customs through time in response to historical circumstances that are contingent on both native and European factors (Watanabe 1990). Among standout examples, Joel Palka (2018) lays out how ancient Maya landscape rituals and the sets of beliefs involved in these practices have been recombined and recontextualized to fit nineteenth-, twentieth-, and twenty-first-century conditions in the Lacandon region of Chiapas and Guatemala. And Judith Zeitlin (2018) discusses the incorporation of Catholic imagery into the persistent material culture of sacred landscapes and shrines in Oaxaca. She also shows how traces of indigenous practices are still evident in the Catholic fairs honoring town patron saints across the Mesoamerican macroregion.

World Systems Studies

While various archaeologists have applied the world systems framework to prehistoric cases, a number of studies based on historical time frames are few. Within that small set, some researchers simply have employed the notion of the world system without engaging the elements of world systems theory. Stanley South et al. (1988), for example, set out to show how the sixteenth-century Spanish colonial settlement of Santa Elena, South Carolina, was linked to the world system. South's meticulously quantitative analysis of artifact types – useful in itself – was tied to a series of assumptions about artifact variability and frequency, but in fact almost all of these were aimed at determining patterns not directly tied to the world system, such as public versus private structures or elite versus laborer dwellings. Only one very simple assumption – that certain artifact types would serve as indicators of the world trade network – was expressly related to the stated theme.

Thomas Charlton et al. (2005) similarly used pottery as an indicator of the Spanish-dominated world system. These researchers compared the ceramics of early colonial Mexico City/Tenochtitlán, the regional center of the externally imposed "Hispanic worldwide empire" (Charlton et al. 2005: 50), with pottery from Otumba, a rural settlement in the Basin of Mexico. In Mexico City/Tenochtitlán, ceramic change was rapid; Spanish and Oriental ceramics were introduced quickly, and locally made indigenous wares showed clear Spanish influence. At Otumba, on Mexico City's periphery, ceramic change was minimal, indicating weaker integration into the Spanish world system.

However, some investigators have considered the systemic effects of world systems processes, which they access by bringing some of the comparative elements of the world systems framework into play. Groover (2005) focuses on a single farmstead in southern Appalachia to show how this region, a subsistence farming backwater in the eighteenth century, became an internal periphery within the economic core in the 1800s. This shift occurred when the immense plantations of the deep south became so dedicated to monocropping cotton that they were no longer able to raise food for their slave labor forces. To fill the gap, Appalachian farmsteads began producing surplus for the plantation market. When the plantation economy declined, partly as the result of westward expansion, production at Groover's farmstead also dropped. Groover also links his work to that of the critical theorists, noting that when his farmstead became integrated into the capitalist market, household space became compartmentalized and ceramic inventories increased. Yet the social processes of urban capitalism were incomplete in this rural periphery since foodways retained their essential folk character.

Alexander's (1999) world systems-based analysis of central Yucatan, on the global periphery of the world system, provides another important point of comparison to core capitalism. She uses written and material evidence to show statistically variable degrees of capitalist market integration among small independent ranchos (small rural settlements), pueblos (small aggregated settlements),

cabeceras (administrative towns), and small cattle haciendas in the nineteenth century. Though market integration was low in all cases, most of the settlements in her study, regardless of size, yielded some evidence of nonlocal, usually foreign goods – evidence that local producers participated, to varying degrees, in the global market system and thus produced some surplus for exchange. Nevertheless, the degree of world systems integration in this peripheral region was insufficient to create the compartmentalized, disenfranchised labor force demanded by industrial capitalism in the core.

Kepecs (2003, 2005, 2018) applies a longue durée world systems approach to the northeast corner of Yucatan state, Mexico. She uses written and material evidence from the late pre-Hispanic era to reveal conditions of incipient capitalism: intensive surplus production, regional and macroregional markets, interpenetrating accumulation, visible macroregional ideology of trade and production, and competition among the Maya merchant kings of several small polities on the northeast coast. The systemic exchange in which these rulers engaged involved bulk goods – fine white Yucatecan salt was traded for cacao grown on the humid plains of the Gulfs of Mexico and Honduras. Specialized labor for the extraction of salt, a highly localized resource, was, in fact, separated from the household context; as in industrial capitalism, rulers or entrepreneurs controlled, to large degree, the means of production. In the early colonial epoch, indigenous workers here amassed great quantities of salt for the Spaniards' profit; yet at the same time, the Maya retained a separate, clandestine economy. In addition to salt harvested for Spanish enterprise, they produced enough surplus to supply their own long-distance exchange circuits. In return for salt they received cacao, incense, and ceramic incensarios produced by other Maya groups in the Guatemalan Petén.

Throughout the first century of Spanish rule, this region was the scene of bloody Maya uprisings; eventually the Spaniards retreated to their administrative centers elsewhere in Yucatan. By examining the trajectory of the northeast area from the late colonial era to the present through the temporal lens of Kondratieff waves – global boom and bust cycles that generally span 40–60 years (Modelski and Thompson 1996) – Kepecs (2018) shows how the region became a backwater in the dominant, Spanish-driven economy but was involved in the economic booms and busts of the world system through illegal exchange with pirates from non-Spanish Europe. Lack of Spanish infrastructure and administration in the northeast led to quasi-isolation; today infrastructure and administration remain weak, and the area is involved in new forms of piracy, including narcotraffic and illegal fishing for sea cucumbers, much desired in Asian markets.

Dialectical Studies

Orser (2011: 539) called for a dialectic approach to the interactions between economics, class, race, and power within both specific sociohistorical contexts and the capitalist world system. Although leaders in the field have advocated this approach for a long time (Leone and Knauf 2015: 4), it has been underutilized until recently. Among the most salient current examples are works by Wurst and Ridarsky (2014) and Dawdy (2010). Wurst and Ridarsky (2014) reveal the contradictions between government narratives and life lived by the poor, using an example from the Finger Lakes National Forest in New York. The region had been settled by small farmers in the nineteenth century. The archaeological record reveals capital investments in the 1870s, increasing diversification of crops, and substantial consumption of consumer goods, including automobiles, well into the 1930s. During the New Deal of the 1930s and 1940s – the government's response to the Great Depression – resettlement programs were created to move farmers off "submarginal lands." The farms Wurst and Ridarsky excavated were purchased by the government and replaced with forest; the displaced farmers were offered "better opportunities" in urban settings. Yet there is no material evidence that these lands were marginal. Instead, by reading the written record "against the grain," Wurst and Ridarsky reveal that the resettlement program was a tool of largely undocumented agricultural class warfare, aimed at appeasing wealthy new industrial agriculturalists who complained that the continuance of small farms would lead to flooded markets.

Dawdy (2010) is interested in the "ruins of modernity" – contemporary urban ruins such as abandoned factories and dying commercial districts, which hold a great deal of underutilized information about economic bust cycles. Considering these sites dialectically and focusing on her own observations of post-Katrina New Orleans, she argues that ruined urban sites are usually cast as negative spaces – but in fact, these sites, released from "the grip of private property relations" (2010: 776), become hotbeds of vibrant art, political activism, and informal economies that often involve illegal pursuits but provide an economic safety net for people who are marginalized in global bust cycles when legitimate jobs disappear (or move from the developed world to Asia, where labor is cheap).

Latin American Research on the Historical Archaeology of Capitalism

Writing from Colombia, Cristóbal Gnecco (2015) takes a critical theory approach to the commodification of heritage sites, aiming to decapitalize archaeology by granting indigenous people agency to interpret ancestral remains according to their own internal logic. In the modern, capitalist world, we separate the past from the present; yet indigenous people do not necessarily frame time in modern terms. Gnecco provides an example: indigenous people living on the Juan Tama reservation on southwest Colombia today see the archaeological remains there – stone sculptures and ceramic pots – as living historical beings who possess the territory and with whom contemporary residents commune. A critical anthropological archaeology of capitalism, Gnecco concludes, must be done from the bottom up – by native people with ties to the land whose non-Western, noncapitalist, nonmodern temporal perspectives must be recognized as fully legitimate archaeological interpretations.

Gnecco is a pioneer of this approach in Latin America; the great majority of Latin American historical archaeologists concerned with capitalism are modernists with Western educations who deal with the issue empirically, though their studies are tightly focused, in contrast to the culture history of the early twentieth century in the USA. For example, Andrews et al. (2006) (the lead author on this entry is a US citizen and teaches in the USA; however, he grew up in Yucatan and is part of a Yucatecan research team) lay out the archaeological record of El Real de Salinas, a late-nineteenth-century port on the coast of Campeche, Mexico, from which salt, dyewood, and other coastal resources were harvested in great quantities and shipped to other parts of Mexico and beyond. This is the only work to date that provides detailed descriptions of productive and shipping infrastructure built to facilitate the export of raw materials from the world systems periphery to the USA, which, by this time, had superseded Britain as the global economic core.

In Argentina, Schavelzon (2002) addresses some of the concerns of both critical neo-Marxism and the world systems framework in his detailed look at the rise of capitalism in Buenos Aires, but he does not address directly the theoretical positions of these approaches. Instead, he documents the rise of the bourgeoisie by focusing on the increasing material evidence of European goods from the sixteenth through nineteenth centuries. Schavelzon notes the incorporation of individual eating utensils following the rise of Britain's Industrial Revolution, but there is no accompanying consideration of whether this phenomenon was linked to a shift toward social isolation or whether that occurred later in the nineteenth century when production in Argentina was industrialized.

Sanoja and Vargas-Arenas (2007) provide a similar, implicitly Marxist reading of the economic culture history of Santo Tomé in Guyana, Venezuela, where Capuchin missionaries from Catalonia, Spain, used slavery and feudal peonage systems to organize indigenous and African labor for the intensive production of agricultural products, silver, and cotton cloth. These goods fed an import/export economy that underwrote capitalist development in Catalonia during the colonial epoch, and after Independence surpluses that had accumulated in mission warehouses were used to finance the development of the modern capitalist state centered at Caracas.

A number of young scholars putting out papers on the Internet also are starting to consider the

historical archaeology of capitalism. For example, Cuba's nineteenth-century wealth was built on slave labor, but the fruits of the island's plantations allowed Cuba's elite to accumulate wealth and abundant goods from the global capitalist market. Until now Cuban historical archaeologists working in Old Havana have not discussed overtly the links between these luxury goods and the capitalist system in Europe and the USA that produced them or addressed the class divisions that arose from this wealth on the island. But one young investigator, Darwin Arduengo-García (2011) points out that the written and material records of Old Havana will allow researchers to follow the steps of Havana's integration into the nineteenth-century world capitalist market.

Key Debates

There is no question that the study of capitalism is a major area of investigation in the field of historical archaeology, though debates about how best to approach the subject remain. Tightly focused empirical studies like those by Andrews et al., Schavelzon, and Sanoja and Vargas make important contributions to the literature without the baggage of explicit theory. This raises the issue of whether a theoretical perspective is always important. In fact, given the ongoing explosion of philosophy-derived, terminologically imprecise, post-processual approaches, some US archaeologists are returning to cultural-historical practice (see Pauketat 2001: 74), albeit with the kind of systematic focus that typifies the Latin American work.

Nevertheless, using theoretical frameworks as a way to organize empirical information and compare it with similar cases can facilitate important insights. The historical archaeology of capitalism has advanced through all three approaches discussed here, though all are subject to critique. There is a fine line between critical neo-Marxism, which takes the investigator's own political consciousness into account when interpreting the past (Leone 2010: 54–55), and phenomenology, a school of post-processual thought in which interpretations are based on the investigator's personal experience (Preucel 1995). Phenomenological research is inherently subjective; Matthews' argument about the colonoware pots, encapsulated above, is a case in point. While the pots, given their archaeological provenience, may well have been used ritually, Matthews offers no information supporting his claim that these rituals were designed to challenge the capitalist order. Rather, that is how Matthews himself, as a twenty-first-century archaeologist looking for ways to challenge the capitalist order, reads the evidence.

Another problem with critical theory is that it often fails to hook the structures of everyday life to the global political-economic forces that created them. Although critical theory and world systems approaches can function together, as the studies by Groover and Alexander, cited above, confirm, many historical archaeologists have yet to grasp how world systems theory actually works. Criticisms abound. To make the world systems approach viable, Orser (2010: 119–120) contends, archaeologists will have to find new ways to use it "that move beyond simply noting that similar artifacts occur in diverse places in the world." Other misunderstandings include the idea that world systems theory fails to provide ways to study indigenous cultures, is unable to deal with issues of resistance, offers no links between past and present, and has no mechanism to account for emotion or failure (Leone and Potter 2003: 4–5). It is indisputable that world systems theory does not account for emotion, though emotions are not artifacts – without direct support from the written record, any interpretation of potsherds that attributes feelings to the possessors of the original pots will be subjective. The rest of the criticisms, however, do not hold up. World systems studies account for failure by considering decline in the context of economic cycles, as Groover's above-cited study shows. Groover, Alexander, and Kepecs are among world systems archaeologists who go considerably beyond finding similar artifacts in diverse places – they deal with the systemic consequences of capitalism, and their studies variably involve indigenous groups, resistance, and change through time.

Future Directions

Leone and Knauf (2015: 8; also Roller 2015: 25) call for an archaeology of the present and the very recent past, and indeed, some of the most dramatic possibilities for relevance lie in material studies of the world in which we live. Dawdy's (2010) consideration of urban ruins of the late twentieth and early twenty-first century in the USA provides a template for a great deal of future work in this vein.

There is tremendous potential for research in the near past in Latin America as well. During the latter half of the twentieth century, for example, leftist rebellions across Latin America threatened US capitalist interests in the periphery. Yet much remains unknown about this clash. Patricia Fournier and Jorge Martínez Herrera (2009) provide a brave road map for a multidisciplinary study, yet to be implemented, of the Tlatelolco massacre that occurred in the Plaza de las Trés Culturas at the heart of Mexico City in October 1968. On the eve of the Olympic Games, slated for the stadium at the National Autonomous University of Mexico, the CIA put down a massive, largely student-led demonstration against Mexico's glaring political-economic injustices. In the name of core capitalism, untold numbers of demonstrators were murdered or disappeared. Almost all of the evidence was covered up by the Mexican government. Fournier and Martínez Herrera (2009: 169) call for forensic anthropologists, archaeologists, and historians to retrieve missing information, to recover historical memory through analysis of material culture, and to finally record the details of state terrorism carried out in the name of protecting US financial interests. Projects such as this have the potential to unmask late-stage capitalism in the periphery and to awaken the public at large to the crucial role of historical archaeology.

Yet recent events do not stand alone. Leone (2010: 7–11) and Alexander and Kepecs (2018) among others call for making the historical archaeology of capitalism socially relevant by connecting the present to the past. This is not always easy; as realized to date, much historical archaeology is not fully diachronic. Leone and Pruitt, in their 2015 study of Wye House cited above, want to link the African-American gardening practices they see in excavated pollen data to African-American gardens in eastern Maryland today. But to date they have only been able to observe these gardens from the outside, which allows nothing more than tentative hypotheses. Similarly, Roller (2015) examines the written and material records of consumerism in the twentieth century. Mass-produced goods are markers of the late-modern (twentieth-century) political economy, which, Roller notes, was successful because of humans' "natural selfish inclinations" (2015: 26). But by starting his analysis in 1917, which he argues is the beginning of mass consumerism, he fails to consider the great time depth of human selfish tendencies; industrially produced luxury and semi-luxury goods (such as British whitewares in the second half of the nineteenth century) were used as markers of competitive economic identity in the nineteenth century (Fournier 2018), and the use of similar (if not factory-made) status items harks back to much earlier periods.

The long-term (longue durée) development of capitalism is a key issue, and since the archaeological record is a palimpsest, studies that follow substantial diachronic trajectories also utilize the full power of archaeology. Schavelzon, and Sanoja and Vargas take a longue durée approach to their empirical investigations of capitalism in Latin America. And a new volume on anthropological historical archaeology in Mesoamerica (Alexander and Kepecs 2018) deals with change in economic, agricultural, and ideological systems – all ultimately aspects of capitalism – from the late pre-Hispanic past through the present. To fully understand the development and persistence of capitalism, more longue durée studies will be necessary.

Capsicums/Chiles: Origins and Development

Linda Perry
The Foundation for Archaeobotanical Research in Microfossils, Fairfax, VA, USA
Department of Geography and Geoinformation Science, Center for Earth Observing and Research, George Mason University, Fairfax, VA, USA

Basic Species Information

Chile peppers are the fruits of Neotropical plants that are classified within the genus *Capsicum* (Fig. 1). At least five different species of chile peppers were brought into cultivation and were eventually domesticated by the indigenous peoples of the Neotropics. These five species are still in cultivation today around the globe, and the pungency of chiles, a result of the chemical capsaicin in the tissues of the fruit and seeds, can range from nearly nonexistent in sweet peppers to searingly spicy in other cultivars (Andrews 1984).

Capsicum annuum is very likely the most widely cultivated species, and common cultivars in the Americas are sweet bell, *poblano*, and *jalapeño* peppers. The species *Capsicum baccatum* includes the cultivar *aji amarillo*, a chile that is integral to Peruvian cooking. *Capsicum chinense* varieties include the *habanero* and Scotch bonnet peppers, both known for their intense heat. *Capsicum frutescens* is the species that includes the famous Tabasco pepper and is considered by some to be wild rather than domesticated. Varieties of peppers like the *rocoto* and *manzano* that thrive in higher elevations are classified in *Capsicum pubescens*, and differ from the other species of peppers in their seed color, a velvety black.

Capsicums/Chiles: Origins and Development, Fig. 1 Various modern cultivars of peppers (four species represented). (Photo by Linda Perry)

Major Domestication Traits

While it is generally agreed upon that the genus *Capsicum* arose in Bolivia, the regions in which each species was initially brought into cultivation and eventually domesticated are subject to debate. Prior to the arrival of humans in the Neotropics, the fruits and seeds of the wild ancestors of each domesticated species of pepper would have been dispersed by birds and other animals (Pickersgill 1984). Thus, the first humans to arrive would have encountered the small, brightly colored fruits over a broad, tropical landscape. A combination of various lines of evidence including archaeological data, phytogeography, and genetic analyses have led researchers to suggest that *Capsicum annuum* was initially domesticated in Mexico or northern Central America, *Capsicum frutescens* in the Caribbean, *Capsicum baccatum* in lowland Bolivia, *Capsicum chinense* in northern lowland Amazonia, and *Capsicum pubescens* in the mid-elevation southern Andes (Pickersgill 1971, 1984; Loaiza-Figueroa et al. 1989; Eshbaugh 1993).

The most solid evidence for the use of chiles by ancient humans is derived from archaeobotanical remains recovered from archaeological sites. Archaeobotanical remains of peppers are typically recovered as large fragments or entire fruits (macroremains) or as microscopic residues that include starch grains from the pericarp tissue of the fruit (microremains). Macroremains of chiles are usually reported from sites in unusual environments including those with arid or waterlogged conditions that allowed for exceptionally good preservation. Where preservation is less than

ideal, microscopic resides of starch grains can be recovered from sediments, ceramic sherds, and lithic processing tools (Perry et al. 2007).

The only sequence documenting the domestication of chiles comes from Mexico. The remains of wild chile peppers recovered from several levels at Coxcatlán Cave in the Tehuacán Valley are the earliest evidence for what would later become an important domesticate in this region (Smith 1967). The analysis of pepper remains from the entire cave records what is believed to be wild chile harvesting beginning about 8,000 years ago followed by the cultivation and eventual domestication of the pungent fruits of *Capsicum annuum* by about 6,000 years ago (Smith 1967). The sequence of cultivation documents changes in the fruit size from small, wild-type forms to larger, cultivated and domesticated landraces.

Microremains of chiles from sites in Ecuador, however, are derived from chiles that were already domesticated by 6,000 YBP (Perry et al. 2007). Because the wild ancestors of chiles do not occur in the local flora, the most likely scenario is that chiles were domesticated elsewhere, prior to this time and were brought into the area by trade or other human interaction. Because five distinct species of *Capsicum* were domesticated in five different areas, and there are few early sites that have yielded remains, there is a great deal more work that needs to be completed to locate the origins of these plants and track their trajectories through human use. Nonetheless, it is clear that chiles were an early domesticate in the Neotropics.

The remains of chile peppers have been recovered from New World archaeological sites ranging temporally from about 8,000 years before present to European contact, and geographically from what is today northern Mexico, to the Caribbean, to coastal South America (for a review, see Perry 2012). Thus, the use of chiles as a spice by human populations has great time depth and was geographically quite widespread prior to European contact.

Further, chiles have been found in sites where groups had different food procurement strategies and population sizes (Perry 2012). The remains of chiles appear first as wild-collected plant foods, then continue to occur in areas where cultivation took place in forest swidden plots, in complex drained field systems, and in both small and large agricultural fields, both nearby and far from settlements. They occur in sites that had a few, seasonal inhabitants, in medium-sized villages, in large permanent settlements, and in ceremonial feasting contexts. Chiles also occur in coastal sites, inland sites, cave sites, open air sites, highland sites, and lowland sites. Clearly, the popularity of chiles transcended time, space, and culture.

Because they are a spice plant, chiles do not occur in isolation in archaeological contexts. They appear in concert with maize, beans, and geophyte food plants, and in the case of microfossil analysis, they frequently occur together on the same tool (Perry 2012). The spice of chiles would undoubtedly be appealing to people who were subsisting on a relatively bland diet of maize, beans, roots, and tubers. These staple crops are plant foods that supply a significant portion of a person's daily calories. Chiles, in contrast, are not staple foods, but are commonly used as vegetables, as condiments, or as a spice.

The exploitation of chiles, a spice, during the earliest periods of occupation in the Americas provides solid evidence that sophisticated agriculture and complex cuisines arose very soon after initial colonization. The widespread geographic and temporal spread of archaeological remains indicates that, once chile peppers became incorporated into local cuisines, they persisted, and both ethnohistorical accounts and modern distributions indicate that humans have never lost their taste for these spicy foods.

Caral: The Sacred City

Ruth Shady
Zona Arqueológica Caral, Unidad Ejecutora, Ministerio de Cultura, Las Lomas de la Molina Vieja, Lima, Peru

Introduction

The Sacred City of Caral-Supe was constructed by one of the oldest civilizations on the planet, created from the organized labor of its settlers, led by a dominant class, in a territory of contrasting geographic configurations.

Many know of Cusco as the capital of the Inca Empire and Machu Picchu as the estate of the last Incas, but few know, even now, that the Sacred City of Caral was built by the first political state to be formed in Peru, 4400 years before the Incas ruled.

The Caral-Supe civilization was forming in America almost simultaneously with those in Mesopotamia, Egypt, India, and China. The inhabitants of Peru were at least 1500 years ahead of those occupying Mesoamerica (where another cradle of civilization has been identified, of six that are acknowledged worldwide) and more than 3000 years ahead of the society that built the well-recognized Mayan cities.

Unlike other cradles of civilization, such as Mesopotamia, Egypt, and India, that interchanged knowledge and experiences, Caral-Supe attained advancement without any precedents, in complete isolation from its contemporaries either in America or the Old World.

In Peru, the forms of economic, social, and political organization of the Caral-Supe people had a strong impact on the history of the area; they transcended space and time, and laid the foundations for the sociopolitical system of much of the population of the Central Andes.

In the north-central zone of Peru, the organizational model designed and implemented by the Supe State determined the actions of individuals for several centuries, in different fields: economic, social, political, and religious.

Key Issues/Current Debates/Future Directions/Examples

The Supe Society at the Dawn of Civilization

Caral is the most significant settlement of the 20 that have been identified along 40 km of the lower middle Supe Valley; each one combines public buildings with a characteristic sunken circular court and groups of domestic units. Caral is not the most extensive, but shows a planned architectonic design and substantial investment in an extensive workforce to construct the pyramidal

buildings. From the size of the settlement, and from the amount of labor invested, it is obvious that they had a hierarchical command system and a unified social organization in the valley. This pattern extended to the valleys of Pativilca, Fortaleza, and Huaura which, alongside Supe, would have constituted the territorial foundations of the original state.

The city of Caral is situated at the entrance to the middle Supe Valley, Barranca Province, at kilometer 184 on the Pan-American North Highway, in the north-central region of Peru. Due to its size and architectonic complexity, it is the most outstanding urban settlement of all those identified in Peru as flourishing between 3000 and 2000 BCE.

Caral covers 66 ha, with distinct core and marginal zones. In the center, the buildings are distributed in two large segments: one high, where one can observe the most imposing pyramidal constructions, a sunken circular court, and two massive public meeting places, as well as the domestic units of the officials and an extensive residential neighborhood. The lower segment has smaller buildings, although they display the same architectonic complexity as the amphitheater, plus a similar residential group, but less extensive. The peripheral zone has many grouped dwellings distributed as an archipelago, in "islets" along the terrace that borders the valley.

Millions of stones were cut and transported to the city for the construction of the public buildings, to remodel their architectonic designs or to cyclically bury them and build anew.

Economic Conditions that Sustained the Life and Work of Supe Society

The technological advances achieved in the areas of agriculture and fishery, in the inter-Andean valleys and on the coast, respectively, influenced the development of a productive force within the societies of the coastal valleys of the north-central region, in particular the Supe. Production of cotton and the manufacture of fiber, destined for a clothing industry and, more importantly, for nets to capture massive amounts of fish, encouraged labor specialization and favored economic complementarities, by means of a permanent exchange of goods between the agricultural and fishing settlements. This enabled the accumulation of production and the social division of labor, specialization, and exchange of goods over short and long distances.

The Social Weave and State Formation

The surpluses derived from production, as much in agriculture as in fisheries, were unequally distributed, to the benefit of the aristocratic lineage and those in charge of the activities that were necessary to guarantee continuance of the system; in this way, north-central regional communities were formed, from farmers and fishermen, or "pachucas," supervised by authorities and "principals," with their respective public buildings for administration and ceremony, their residential enclaves, and their territory of economic production.

This productive surplus favored the populations of the middle Supe Valley, being better situated for the exchange of goods. The aggregated value from manufacturing the cotton fiber and processing the anchovies and sardines, destined for exchange, enriched and augmented the prestige of the "principals" in charge of interethnic commerce. Among the authorities, the "hunu" was chief, the lord of lords of the valley and coastal settlements, and above all these "hunus" would be the lord of the whole territory between the Valleys of Santa and Chancay. This model of political organization would continue for some time in pre-Hispanic Peru.

The original state of Supe managed to mobilize large quantities of labor and, through complex relationship networks, to garner the benefits of the production surplus from an extensive territory, which included, apart from the coastal region, the Huaylas Corridor, the Huallaga, and the Marañón (the Labarynth).

The majority of the population made up the lower social strata, dedicated to agricultural or fishing activities, and to all the jobs demanded of them by the State.

The Importance of Knowledge in Civilizing Development

Under these socioeconomic conditions, there developed the sciences, technology, and the arts.

Their knowledge of astronomy, geometry, arithmetic, biology, medicine, and so on was applied to climate forecasting, the development of a calendar, the construction of architectonic works, soil management through construction of irrigation and drainage channels and the fitting-out of small farms, the genetic improvement of plants, the treatment of some afflictions and diseases, to public administration, and to the manufacture of artifacts for ceremonial, commercial, and luxury purposes. These advances in knowledge, carried out by specialists, also gave them power and improved the lifestyles of the north-central people at the dawn of civilization.

Today we can marvel at the urban orderliness, the architectonic works, and the geoglyphs that predated, by over 3000 years, the famous Nasca lines; the wall ornamentation, the musical instruments, the manufactured textiles, and the personal adornments; and the genetic variety of their produce, as represented by over a hundred small statues of unbaked clay.

The Role of Religion

An elaborate system of beliefs, ceremony, and rituals pervaded the societies of the valleys situated between Santa and Chancay, and of the mountains and jungle on their borders, articulated by the primitive political State of Supe, or attracted by its prestige. Universal mythological and symbolic complexes arose.

In the absence of a military unit, religion became the force of social cohesion and control. Life and the daily routine of the population passed by, dedicated to subsistence production as well as support for the gods, the authorities, the officials, and the public servants; at the same time they carried out construction work and the interment and remodeling of temples, for which they were periodically summoned.

Caral and Social Self-Esteem

The primary contribution of Caral to present-day society is in the area of historical knowledge, to show how ancient this civilization is, in Peru and in America, and so to modify current conceptions of the human condition on this planet.

In the more concrete case of this, our country, research at Caral allows us to understand the responses to life developed by societies that inhabited this territory before we did; we can take full advantage of the positive experiences and cast aside the unsuccessful.

From a cultural perspective, Caral is destined to become one of the most important instruments for elevating the self-esteem of Peruvians and the most prominent symbol of national identity, due to its being the first civilization, the oldest in America, and the model of the sociopolitical organization that other societies would develop in later times, in the territory of Peru. It is clear to us the creative capacity of the inhabitants of this humble territory; that with effort and organization, they managed to become a civilized state, a millennium and a half before the other populations of the continent.

From the economic point of view, the value proposition of Caral comes via the activities of research, consolidation, and restoration of its imposing monumental structures; these will convert it into a first-class tourist destination on a national and international scale, and into a source of considerable income, which will improve the living conditions of the local population and of the country in general. Due to its historical, cultural, and economic value, allocating funds to Caral is not an expense but an investment which will contribute to the development of the whole nation. We are confident about the changes in attitude: the acknowledgement of the value of our millennial history that should make every Peruvian self-affirmed and able to forge on with confidence, centered in the same vision of development, to the benefit of all of us that make up this nation.

Cultural Heritage as the Basis for Promoting Socioeconomic Development

The Caral-Supe Archaeological Zone management believes that the valley's archaeological wealth can promote the socioeconomic development of the population in their diverse aspects. To achieve that, it has proposed a master plan

of organized development with projects in various fields: agrarian, systemization of the basin catchment area, reforestation, artisan and manufacturing production, environmental sanitation, and tourist services. It is believed that this important cultural resource can be valued in an adequate social context. Then the current population will be able to identify with it as the source from which it derives a better quality of life and will not convert into a mere spectator of the well-being of visitors. With this in viewpoint, we work to obtain the support of the diverse sectors of government: central, regional, and local, as well as secular society, so that by uniting this integrated vision of development can be made reality, to the benefit of the archaeological heritage and of the current population that lives alongside.

With this outlook, the Caral-Supe Archaeological Zone management carries out archaeological excavations at Caral and at other sites on the outskirts, and contemporary to this; it studies and analyzes the materials obtained; it develops a permanent monitoring and conservation program for the architectonic structures of the site; it publishes reports both scientific and informative; it designs tourist visitor circuits; it organizes events to adequately raise awareness of the historic and cultural importance of the place; and it promotes the integrated development of the local and national populations.

The Caral Archaeological Zone

The Caral Archaeological Zone (ZAC) is a Peruvian State institution which, for 18 years, has been working in many parallel endeavors: in the scientific study of the archaeological sites of the origins of civilization, namely, Caral, Chupacigarro, Miraya, Lurihuasi, Allpacoto, Pueblo Nuevo, El Molino Era de Pando (Supe, Barranca), Áspero (Supe Puerto, Barranca), and Vichama (Végueta, Huaura); in the physical preservation of the monuments; in the value proposition of these as tourist destinations; and in the search for ways to apply an integral program for fomenting the socioeconomic development of the surrounding population centers.

Our ultimate goal is to convert the rich cultural heritage of the Caral civilization, the most ancient in America, into the axis that drives development of better living conditions for present-day society. These activities were acknowledged on an international level when, at the 33rd Convention of the Committee of World Heritage of UNESCO, the Sacred City of Caral was named a Cultural Heritage of Humanity.

Cárdenas, Mercedes

Rafael Vega-Centeno
Pontificia Universidad Católica del Perú, Lima, Peru

Basic Biographical Information

Mercedes Cárdenas is a Peruvian archaeologist who dedicated her career to the study of Andean pre-Hispanic cultures of the Peruvian central coast. She was born at Trujillo in 1932 and studied at the Pontifical Catholic University of Peru (PUCP) receiving her degree of Doctor in History and Archaeology. Later, she became an associated researcher of the *Instituto Riva-Agüero* of the PUCP and worked under the direction of Josefina Ramos de Cox, excavating at the site of *Tablada de Lurín*, near Lima. In 1974, she convened the archaeology seminar of the *Instituto Riva-Agüero* and continued her research project at *Tablada de Lurín* until 1989. She also undertook a research project on the use of maritime resources in ancient Peru under the sponsorship of the Volkswagen Foundation and conducted survey and

excavations at the Sechura Desert in Northern Peru. She was a professor at the Archaeology Program of the PUCP. She died in 2008.

Major Accomplishments

Dr. Cárdenas research has contributed to increasing our knowledge about coastal societies of the Andean region. Her work at the site of Tablada de Lurín has allowed the recovery of information on hundreds of burials from one of the largest cemeteries of the Central Coast (1980, 1986, 1989). Her work on maritime resources and their changes through time was a pioneer study of Andean biofauna that is still a major reference for researchers (1979). She also pioneered research on the arid region of Sechura (see Cardenas 1991).

Caribbean Historical Archaeology

Helen Blouet
Department of Sociology and Anthropology, Utica College, Utica, NY, USA

Introduction

Caribbean historical archaeology comprises the study of Amerindian, European, African, and Caribbean societies and cultures from fifteenth-century European exploration to the present day. Key areas of research include multi-scalar interpretations of (1) early Spanish and European colonialism and Amerindian responses to European emergence in the region; (2) transatlantic slavery and the African diaspora; (3) plantations and other settings of production, trade, control, terror, resistance, and community; (4) African cultural survivals; and (5) Creolization and ethnogenesis. More recently, researchers have focused attention on little-investigated peoples and circumstances, such as enslaved and enslavers living on relatively small plantations and properties; free populations of color; indentured servants; interactions within and between seemingly distinct groups; under-investigated spaces and places of rural, urban, inland, and coastal landscapes; and emancipation and post-slavery periods. The field also contributes to advancements in archaeological applications of digital modeling and spatial analysis. The methods, theories, and topics pursued by Caribbean historical archaeology have helped establish cultural resource management and historic preservation policies, as well as community-based collaborative outreach, that in turn inform islands' cultural, political, and economic identities across the region and around the world.

Definition

Caribbean historical archaeology encompasses archaeological and anthropological studies of Amerindian, European, African, Asian, and

Caribbean societies and cultures from before fifteenth-century European exploration to the present day. Studies routinely combine archaeological survey, excavation, and site and artifact analysis with interpretations of historic documents, ethnohistory, and oral history. The discipline of Caribbean historical archaeology derives in part from ties with Caribbean Amerindian archaeology of the protohistoric period, North American historical archaeology, and Caribbean sociocultural anthropology, all of which address some aspects of the research foci listed above. Historical archaeology in the Caribbean increasingly involves a mix of West Indian and non-West Indian nationals, including scholars, cultural resource managers, members of for-profit and not-for-profit organizations, descendant communities, students, and the general public.

Key Issues/Current Debates/Future Directions/Examples

Key issues or areas of research include topics that demonstrate the diversity of the Caribbean's past and present. Over the last two decades, the number of volumes and reviews showcasing Caribbean historical archaeology has grown. Works such as "A Sea of Diversity: Historical Archaeology in the Caribbean" (Armstrong and Hauser 2009), "New Directions in Caribbean Historical Archaeology" (Armstrong 2013), and *Archaeologies of Slavery and Freedom in the Caribbean: Exploring the Spaces in Between* (Bates et al. 2016) outline the Caribbean Basin's past and present research trends and developments in historical archaeology and cultural resource management. Though such comprehensive overviews are relatively recent, archaeological research in the area has existed for over a century, and today the multidisciplinary field exemplifies the region's rich historical complexity and current sociocultural diversity (Armstrong 2013: 527).

Projects have interpreted the remains of sites and material culture reflecting the emergence of and contact between peoples and cultures derived from the Americas, Europe, Africa, Asia, and the Caribbean in contexts of colonialism, trade, globalization, power, slavery, and freedom (Armstrong 2013: 527). Three of the discipline's longest-standing research foci concern (1) Amerindian sociocultural actions and identities in response to and manipulation of European contact; (2) European colonialism, control, and compromise of people and resources; and (3) the endurance of enslaved and free African-descent communities and their fights for liberty. These three areas of research developed out of studies evaluating pre-European contact Amerindian settlements and occupations in the Caribbean. By the early twentieth century, scholars of Amerindian Caribbean lifeways reconstructed the cultures and societies of Taínos and their predecessors by working back from historical period Amerindian sites and European documents containing ethnohistoric information (Curet and Hauser 2011). They connected this data to earlier occupation evidence to interpret change and continuity from the earliest periods of occupation to the post-European contact era. There next emerged by the mid-twentieth-century investigations of European, primarily Spanish, exploration, colonization, and adaptation to diverse environments in the region. Scholars have attempted to reconstruct landfalls and early settlements devised by Christopher Columbus, his envoys, and subsequent expeditions in Hispaniola (the island comprised of the Dominican Republic and Haiti) (Ewen 1991), Florida (Deagan 1988) and other locales.

Though not completely, European explorers and settlers documented their presence in the Caribbean through official and personal records (Armstrong and Hauser 2009: 588). Accounts from the likes of settlers, travelers, military and government personnel, clergy, property owners, and traders contain insight into daily life, unique events, and physical and social surroundings that remain useful to historical archaeology interpretations. Certain pieces, such as Jeremiah Murphy's 1859 description of Jamaica's Fort James, voiced the desire to preserve and restore historic buildings and landmarks (Armstrong and Hauser 2009: 588). About the same time, the Natural History Museum of the Jamaican Society (founded in 1830) and the Institute of Jamaica (founded 1879) increased efforts to document landscapes,

architecture, and settlements, most of which pertained to European military sites, plantations, trade networks, and places of religious worship (Armstrong and Hauser 2009: 588). Such efforts sparked early twentieth-century preservation attempts elsewhere in the region, such as at the colonial forts of El Morro in Puerto Rico, Brimstone Hill in St. Kitts, and the Citadel in Haiti (Armstrong and Hauser 2009: 588). Since such early efforts, increased numbers of diverse archaeological, cultural, and historical sites of interest are analyzed and protected, despite differences in the amounts of preservation and analysis carried out on each island (Siegel and Righter 2011). Without such long-standing interests in Caribbean cultural history, current understandings and preservation programs might not be as rich or as well supported.

By the 1960s and 1970s, historical archaeology and anthropology in the Caribbean gradually included research on enslaved and free communities of African descent. This was in part a product of many Caribbean islands gaining independence from their colonial administrators, as well as African-descent communities pushing for increased civil liberties. Research and academic institutions also intensified their work on local history and culture. Through these processes, island nations developed a focus on understanding and celebrating Creole and African-derived elements of local history, culture, and society (Armstrong and Hauser 2009: 591–593). By the 1980s and 1990s, increasing numbers of projects focused on the African diaspora in the Caribbean and investigated the sites and experiences of enslaved and free people of African descent, including material, spatial, and sociocultural impacts of plantation economies, African slave trade and slavery, emerging freedom and emancipation, and the arrival and influence of Asian laborers and migrants.

Today, research questions are numerous and encompass broad categories of investigation. These include material and industrial transformations in the production of the following: sugar cane and its by-products (i.e., sugar, molasses, rum, etc.); coffee, indigo, and cotton agriculture; imported ceramics and goods; and local craft and ceramic production (see Armstrong and Hauser 2009 for specific studies). As much of this research indicates, material studies of plantations and colonial industries are closely tied to a second category of research on socioeconomic and sociocultural shifts in free, enslaved, and emancipated societies from diverse backgrounds. For instance, the production of sugar, coffee, and ceramics placed free, enslaved, and emancipated peoples of European, African, Asian, and Caribbean descent in complex and fluctuating negotiations of power over personhood, community, labor, goods, behaviors, and interactions (see Armstrong and Hauser 2009; Armstrong 2013). In addition, James Delle, Mark Hauser, and Douglas Armstrong edited the volume, *Out of Many, One People: The Historical Archaeology of Colonial Jamaica* (Delle et al. 2011). This piece showcases projects from the last three decades that have addressed diversity, change, and continuity in Jamaica's politics, economies, and societies – enslaved, free, and emancipated.

Caribbean historical archaeology also interprets site remains of Maroon communities or groups who escaped slavery and created autonomous settlements. Kofi Agorsah and the Maroon Heritage Research Project work closely with current Maroon communities in Jamaica and Suriname to document their heritage, while other Maroon projects occur elsewhere in the region (Agorsah 2013). Furthermore, the discipline is informed by extensive underwater projects that seek to understand the relevance of submerged sites, ships, and material culture. One such project, organized by Donny Hamilton (2016), concerns work on Port Royal, Jamaica.

Within the research categories briefly outlined above, Caribbean historical archaeologists and other groups interpret fluctuating structures and identities of personhood, community, race/ethnicity, gender, age, class, and religion within Amerindian, European, African, Asian, and Caribbean contexts. They evaluate such topics from multiple vantage points encompassing at least one or several of the following: households, camps, villages, factories, plantations, workshops, port towns, cemeteries, places of religious worship, military posts, transportation networks, and sites of

resistance (Armstrong and Hauser 2009). In light of the diversity in peoples, places, and objects, scales of analysis in Caribbean historical archaeology are increasingly designed to interpret multivalent contexts, meanings, and relationships derived from local, regional, and global processes (see Armstrong 2013 for multi-scalar studies).

New Directions

Research is ongoing in many of the arenas described above and includes new trajectories that expand on current data sets, methods, and constituents involved. More recently, research and outreach programs have focused on previously untold or under-told stories of rural, urban, inland, and coastal spaces, their captive and free residents, and the economic, social, traumatic, and resistance activities that took place there. *Archaeologies of Slavery and Freedom in the Caribbean: Exploring the Spaces in Between* (Bates et al. 2016) highlights recent studies focusing on under-examined areas, the "spaces in between" (2016: 1), the "plantation core" (2016: 21), or common focal points of Caribbean historical archaeology. While popular research themes include European exploration and colonialism; enslaved life, suffering, and resistance on large plantations; landscapes of trade, community, and control; searches for African cultural "survivals"; and Creolization and ethnogenesis, projects from the last decade or so aim to build on and refine such themes while shedding new light on under-explored entities such as caves, fields, and provision grounds; diverse rural and urban slavery contexts including enslaved villages, foodways, and market activity; "poor white" and free black communities; interactions between different groups and communities; uses of religion and ritual especially in the context of burial; military settings; emancipation; and post-emancipation (Bates et al. 2016; see also Ahlman n.d.; Curet and Hauser 2011).

Projects of Caribbean historical archaeology also currently consider the importance of interpreting transformations in Caribbean city centers and towns and assessing the relationships between urban and rural contexts. Caribbean historical archaeology reveals that port and market towns acted as important loci for the exchange of goods, labor, and information for free, enslaved, and emancipated people. Towns such as Charlotte Amalie, St. Thomas; Road Town, Tortola; Port Royal, Jamaica; Havana, Cuba; and Bridgetown and Holetown on Barbados connected urban and rural residents and visitors to the same city markets (see Armstrong and Hauser 2009; Armstrong 2013 for specific studies). Urban centers and market towns provided terrestrial and maritime jobs and services often unavailable in plantation and rural contexts. Finally, local communities and resources directly and indirectly attached themselves to those in Europe, Africa, the Americas, and Asia through transatlantic trade, the success of which depended on the state of Caribbean ports and market towns.

Comparisons of diverse and changing Caribbean spaces benefit from digital modeling tools and spatial analysis (Reid 2008). Geographic Information System, or GIS, allows cultural resource managers, researchers, and the general public to effectively combine multidisciplinary and disparate evidence, such as maps, images, written records, and material evidence, into spatial and chronological databases from which they test inquiries, produce multifaceted maps, and expose creative thought on transformations in Caribbean environments, land use, and human interactions. The use of spatial analysis and modeling tools in Caribbean historical archaeology is gradually improving preservation collaborations, communications, and procedures across many islands for the benefit of local and visitor populations and stakeholders (see Ahlman n.d. for specific studies). In addition, Caribbean cultural resource management provides the region with invaluable training, jobs, economic boosts, and deeper understandings and connections to Caribbean pasts, presents, and futures (Siegel and Righter 2011).

Finally, a necessary part of Caribbean historical archaeology involves developing community-based and collaborative public programs informed from their beginning by broad-based local and descendant communities, members of whom may reside on or off the islands (Battle-Baptiste 2017). Since members of such contemporary groups are closely tied to Caribbean

history and archaeology through kinship, ethnicity, and culture, their central and direct inclusion is paramount for the benefit of local communities through the promotion of their own conceptualizations of the past, in particular stories of creating and pursuing personal and professional opportunities, as well as accounts of resisting and transforming legacies of adversity such as colonialism, enslavement, and discrimination (Haviser 2015). Providing detailed and numerous accounts of more recent history, then, increases access to and involvement in public outreach by advancing community-based efforts to build on and question regional, national, and international pasts and presents (Gonzalez-Tennant 2014). Such accounts, in some cases referred to by locals as "real history" because they or their contemporaries experienced it, fill in and complement information discovered and interpreted from primary and secondary historical and archaeological sources (Battle-Baptiste 2017). In this sense, community-based and collaborative oral histories, archive research, mapping projects, and archaeology can significantly inform broader Caribbean histories as well as identities, actions, and events in contemporary societies. In light of the aftermath of destructive hurricanes that occurred in the Caribbean in 2017, archaeology that brings together descendant and local communities with research and historic preservation teams, as well as government entities, has the potential to more broadly and efficiently assess and address damages to historical and cultural resources that increasingly occur due to gradual and rapid deterioration, including impacts of climate change and natural disasters such as tropical storms, hurricanes, earthquakes, and tsunamis. To conclude, Caribbean historical archaeology provides transformative and applied learning and professional opportunities in the region at local, regional, and global scales.

Caribbean Maritime Archaeology

Margaret E. Leshikar-Denton
Cayman Islands National Museum, Grand Cayman, Cayman Islands

Introduction and Definition

Maritime archaeology in the Caribbean Sea involves the study of past people and cultures through the study of objects and features discovered in the underwater and maritime landscapes of the region. It frequently involves archaeology practiced in underwater environments, such as oceans, seas, bays, lakes, rivers, springs, marshes, and cenotes; such submerged environments require the use of specialized tools, although the archaeological research objectives remain similar to those used on land (Leshikar-Denton and Luna Erreguerena 2008a, b; Leshikar-Denton 2011; Leshikar-Denton and Scott Ireton 2013).

Historical Background

In the Caribbean region, there are prehistoric and historical heritage sites that reveal a tapestry of intercultural experiences. From the sixteenth century forward, shifting waves of European explorers, conquerors, and settlers, indigenous and African-enslaved laborers, passing merchants, and colonial powers interacted

and influenced the development of the rich, multilingual cultures of today. Among Caribbean maritime heritage sites are settlements and defensive fortifications, fresh water procurement features, lighthouses and navigational aids, fishing areas, anchorages, careening places, ports, harbors, wharves, bridges, shipbuilding sites, shipwrecks, shipwreck salvage sites, and aircraft lost at sea. Sites range from cenotes and eroded coastal features to remains of catastrophic shipwrecks and earthquakes, at times with exceptional levels of preservation of cultural material (Smith 2000, 2018; Leshikar-Denton 2002, 2004, 2011, 2020; Echeverria 2004; Pateman 2004; UNESCO 2004; Grenier et al. 2006; Guibert et al. 2019; Keith 2006; Leshikar-Denton and Luna Erreguerena 2008a, b; Gray 2008; Hamilton 2008; Hanselmann 2019; Harris 2008; Leshikar-Denton and Scott-Ireton 2008, 2013; Nagelkerken and Hayes 2008; Nagelkerken et al. 2008; Sadler 2008).

The research potential for archaeological sites in the Caribbean is significant, but their heritage value can be overshadowed when commercial interests divert attention to the possibility of treasure on historical shipwrecks that they wish to exploit. The situation poses a constant threat to the archaeological heritage of the Caribbean region, and a challenge to its protection and management.

Key Issues and Current Debates

The Caribbean Sea encompasses English-, Spanish-, French-, and Dutch-speaking countries, some of which are independent and others that are in various levels of dependency, resulting in cultural, linguistic, and legislative differences among them. Yet they share elements of a common maritime heritage. In today's global world, these Caribbean countries are uniting and working toward establishing common goals in many areas, not the least of which is in attention paid to their underwater and maritime cultural heritage, especially for the benefit of Caribbean culture, education, and tourism (Leshikar-Denton 2002, 2011; UNESCO 2004; Leshikar-Denton and Luna Erreguerena 2008a, b; Leshikar-Denton and Scott-Ireton 2013).

In 1997, Caribbean countries formed a technical commission on underwater cultural heritage (UCH) known as the Latin American and Caribbean Group (GRULAC). GRULAC met in Santo Domingo, Dominican Republic, in 1998 and 1999, in preparation for a series of expert meetings held by UNESCO in Paris between 1998 and 2001. They united in support of the 1996 ICOMOS *International Charter on the Protection and Management of Underwater Cultural Heritage*, a charter defining best professional practice (International Council on Monuments and Sites 1996). At the Paris meetings, at which GRULAC was influential, 88 countries adopted the 2001 UNESCO *Convention on the Protection of the Underwater Cultural Heritage*, which establishes an international legal framework (United Nations Educational, Scientific, and Cultural Organization 2001). Since that time, worldwide regional UNESCO meetings have encouraged countries to ratify the 2001 Convention. Jamaica hosted two regional meetings in 2002 and 2011, and a capacity-building training course in 2012. Saint Lucia was the first Caribbean nation to ratify the 2001 UNESCO Convention; the country hosted subregional UNESCO meetings in 2003 and 2008 to assist and inform Eastern Caribbean countries about the benefits of this international legal instrument. Success in the area is due in part to the efforts of the Saint Lucia Archaeological and Historical Society, an organization with a long history of professionally addressing the island's terrestrial archaeological heritage, and a leader in advocacy for ethical underwater and maritime archaeology in the subregion.

Considerable information is available on the 2001 Convention on the UNESCO website (http://www.unesco.org/new/en/culture/themes/underwater-cultural-heritage/2001-convention/), including its Text, Annex, States Parties, history and development, coming into force, worldwide educational efforts, capacity building strategies, and subsequent events. The 2001 Convention entered into force on 2 January 2009. There have been seven sessions of the Meeting of States Parties in Paris between 2009 and 2019, and ten

meetings of the Scientific and Technical Advisory Body appointed by the States Parties to assist in technical guidance.

Operational Guidelines for implementation of the Convention were adopted in 2013 and 2015. To ensure proper implementation, States Parties are to establish competent authorities, or reinforce existing ones. The UNESCO Secretariat works with a wide network of experts and institutions in Latin America and the Caribbean (LAC) and worldwide that assist member states in development of capacities at regional, national, and local levels. Mexico is a leader in this area, and works to provide workshops and training grounds to assist in further capacity building throughout the LAC region.

The 2001 Convention entered into force on 2 January 2009. At present GRULAC countries represent 20 of the 61 ratifications on record: Antigua and Barbuda, Argentina, Barbados, Bolivia, Costa Rica, Cuba, Ecuador, Grenada, Guatemala, Guyana, Haiti, Honduras, Jamaica, Mexico, Panama, Paraguay, Saint Kitts and Nevis, Saint Lucia, Saint Vincent and the Grenadines, and Trinidad and Tobago. The Caribbean countries are now discussing the benefit of establishing compatible national legislation, and have asked the ICOMOS International Committee on Underwater Cultural Heritage (ICUCH) and UNESCO for guidance. Clearly, the 1996 ICOMOS Charter and the 2001 UNESCO Convention are powerful international instruments that lay the foundation for protection and management of the world's UCH. Their endorsement by a growing number of Latin American and Caribbean countries sets a positive example for countries worldwide to take action to identify, protect, and manage it, regardless of their political and economic situations.

In previous publications, brief case studies have appeared by country for many Caribbean islands: the British Overseas Territories of Anguilla, the Cayman Islands, and the Turks and Caicos Islands; the French islands of Martinique and Guadeloupe; the Dutch islands of Saint Maarten, Saint Eustatius, Saba, Curacao, and Bonaire; the Commonwealth of Puerto Rico, a territory affiliated with the United States; independent countries in the Greater Antilles, including the Bahamas, Cuba, the Dominican Republic, Haiti, and Jamaica; and independent countries in the Lesser Antilles, including Barbados, Dominica, Grenada, Saint Kitts and Nevis, Saint Lucia, Saint Vincent and the Grenadines, and Trinidad and Tobago (Leshikar-Denton 2002, 2004, 2011; UNESCO 2004; Leshikar-Denton and Luna Erreguerena 2008a, b; Leshikar-Denton and Scott-Ireton 2013).

Emerging Themes

Island nations are working to develop research and preservation programs to protect, manage, and interpret sites and to promote heritage tourism. They are exploring issues of proper uses of heritage and negotiating approaches from commercial salvors. Emerging themes in Caribbean maritime archaeology include heritage legislation, management, research, meaning to descendent communities, and international perspectives and future directions. Not all Caribbean countries have experience in research, protection, management, and interpretation of UCH, but there is a growing regional concern that commercial exploitation is not beneficial. Caribbean people are exploring and adopting principles like creativity in managing cultural resources and cooperation in sharing knowledge, technical skills, and professional expertise. Many recognize the value of asking for and accepting professional archaeological assistance from outside of the region, but there is a growing understanding that sustainability must come from within the Caribbean islands themselves (Leshikar-Denton and Luna Erreguerena 2008a, b; Leshikar-Denton 2011).

Heritage Legislation

Among Latin American and Caribbean countries, Mexico, Argentina, and the Cayman Islands are exemplary in not having granted permits to salvors in the past quarter-century, and Argentina has achieved specific national legislation to protect UCH. In the countries of Bermuda (often grouped with the Caribbean), the Turks and Caicos Islands, Jamaica, and the Dominican

Republic, where professional archaeological work has achieved success, the governments have also granted permits to salvors in the past. Bermuda, however, notably enacted the Bermuda Historic Wrecks Act (2001), compatible with the 1996 ICOMOS Charter and 2001 UNESCO Convention. More and more countries are waking up to the need to establish similar compatible legislation. A more comprehensive overview is available in Leshikar-Denton and Luna Erreguerena (2008a, b).

Heritage Management

Political, economic, and social factors in the Caribbean have meant that heritage management is less than ideal. Caribbean countries, nonetheless, are using traditional and creative means to achieve progress, whether through governmental or private means. In addition to using legislative approaches, efforts exist to: discourage treasure hunting; create site inventories; mitigate impact to endangered sites; protect and interpret sites in situ as a first option; excavate when scientific objectives justify it, and when there is adequate funding, professional staff, and provisions for documentation, conservation, curation, and reporting, and plans to share results of research with the public through museum exhibitions, the media, and publications. In the Caribbean, sustainable economic and tourism objectives go hand-in-hand with successful promotion to protect and manage heritage sites (Leshikar-Denton and Luna Erreguerena 2008a, b). In the Cayman Islands, for example, a Maritime Heritage Partnership launched a land-based Maritime Heritage Trail in 2003 that consists of 36 sites located around the coastlines of three islands, highlighting a range of themes (e.g., early explorers, maritime place-names, historic anchorages, shipwrecks, wrecking practices, lighthouses, seaside forts, shipbuilding, turtle-fishing, and hurricanes); plans are underway to create shipwreck preserves on robust Cayman Islands shipwreck sites. Similar land-based trails are being created in Jamaica and Anguilla, the wreck of the SS *Mediator* is being interpreted in situ in Curacao, while the Dominican Republic has created underwater museums featuring artifacts from shipwrecks that were replaced on the seabed and interpreted for divers and snorkelers.

Archaeological Research

Archaeological research is on-going in island countries bordering the Caribbean Sea, as well as in the coastal Caribbean countries of Mexico, Central America, and South America. Work by regional researchers, as well as teams from overseas academic institutions in the United States, Canada, Great Britain, France, the Netherlands, and Spain, among other countries, is contributing to a growing body of knowledge. The following summary provides a glimpse into archaeological work that has been accomplished (Smith 2000, 2018; UNESCO 2004; Leshikar-Denton 2002, 2004, 2011, 2020; Echeveria 2004; Pateman 2004; Grenier et al. 2006; Keegan and Hofman 2017; Keith 2006; Leshikar-Denton and Luna Erreguerena 2008a, b; Gray 2008; Hamilton 2008; Hanselmann 2019; Harris 2008; Leshikar-Denton and Scott-Ireton 2008, 2013; Nagelkerken and Hayes 2008; Nagelkerken et al. 2008; Sadler 2008).

With the probable exception of the Cayman Islands and Bermuda, aceramic- and/or ceramic-age peoples prehistorically occupied most Caribbean islands; current archaeological research is providing theories as to their origins and routes of migration into the region. One thing is certain, the settlers traveled to the islands using watercraft; by1492, when Columbus first sighted land, the people who came to meet him paddled out in dugout canoes. These Caribbean seafarers were adapted to aquatic navigation and coastal settlement and procured marine resources, as generations had done before them. In 1995, the University of South Carolina's Institute of Archaeology and Anthropology, at the request of the government of the Bahamas, recovered a ceremonial Lucayan canoe found in Stargate blue hole (a submerged cenote) of Andros Island. In 1996, researchers discovered a Lucayan paddle of about CE 1100 in North Creek, Grand Turk; they assessed its origin to be associated with a nearby outpost of the Taíno from Haiti. The Turks and Caicos National Museum displays this paddle, one of only two such paddles from the Bahamian

Archipelago. In the Dominican Republic, Indiana University and Pan-American Consultants investigated a prehistoric plaza and a cenote containing Taíno artifacts at Manantial de la Aleta. In 2008, the Puerto Rican *Instituto de Investigaciones Costaneras* (IIC), the Centre for Maritime Archaeology and Conservation (CMAC) at TAMU, and the Institute of Nautical Archaeology (INA) surveyed the northern coast of Puerto Rico between Loíza and San Juan Bay. The multi-organizational team located early sites in an area where pre-Columbian settlements existed and over 66 ships were lost.

During four Spanish voyages between 1492 and 1504, Columbus achieved the earliest recorded European explorations of the Caribbean. He lost ships during these journeys: the nao *Santa María* during the first voyage, and the caravels *Mariagalante, Gallega, San Juan*, and *Cardera* during the second, all off the north coast of Hispaniola; and during the fourth voyage, the caravels *Gallega* at Rio Belén and *Vizcaína* at Portobelo, Panama, as well as the caravels *Capitana* and *Santiago de Palos*, both run aground in 1503 in St. Ann's Bay, Jamaica. Since the early 1980s, INA has launched surveys and test-excavations to locate remains of Columbus' ships in Hispaniola, Jamaica, and Panama, while Ships of Discovery has searched for *Gallega* in Panama. Indiana University and Pan-American Consultants have worked cooperatively in a quest for Columbus' ships off Hispaniola.

In the Caribbean, investigators have discovered the unidentified remains of early sixteenth-century ships of exploration and discovery. INA teams investigated three wrecks in the 1980s, all providing clues to a ship-type known as the caravel: the Molasses Reef Wreck in the Turks and Caicos Islands; the Highborn Cay Wreck in the Bahamas; and cooperatively with the Mexican *Instituto Nacional de Antropología e Historia* (INAH), the Bahía Mujeres Wreck located off the northeast coast of the Yucatan Peninsula. The Molasses Reef Wreck, dating to the 1520s, is presently the earliest shipwreck discovered in the Western Hemisphere. Archaeologists excavated the vessel between 1982 and 1985, and initiated conservation treatments on the artifacts. From 1988 forward, Ships of Discovery took over conservation treatments and, working in cooperation with the Turks and Caicos National Museum, prepared an exhibition that today forms the central exhibition of the National Museum. In cooperation with INAH in the 1990s, they undertook additional excavation on the Bahía Mujeres Wreck. Meanwhile, other investigators discovered the sixteenth-century vessel known as the St. Johns Bahamas Wreck on the Little Bahama Bank. Early colonial shipwrecks are also known to exist in Cuban waters, such as the Cayo Ines de Soto Site, thought to have sunk in 1555–1556. Researchers from the abovementioned institutions have further investigated a number of the abovementioned sites in recent years.

Sixteenth-century European navigators learned that it was advantageous to follow prevailing winds and ocean currents when sailing to and from the New World. Ships entering the Caribbean through the Lesser Antilles could exit through the Windward, Mona, and Anegada Passages, or maintain a westward course to the Leeward Passage, by which ships would exit through the Yucatan Channel, enter the Gulf Stream, and follow the currents through the Straits of Florida out into the Atlantic for the return passage to Europe. European powers soon established colonies and seaborne trade networks in the West Indies. Until the latter-seventeenth century, Spain claimed a monopoly on all New World territories that were sighted during the Spanish voyages. The country depleted the supply of precious metals in the West Indies, and then exploited the gold and silver resources of Mexico, Bolivia, and Peru. Mexico City displaced Santo Domingo on Hispaniola as Spain's main administrative center in 1535, and Spain created a second center in 1544 in Lima, Peru, while Cuba, located adjacent to the Leeward Passage and Straits of Florida, remained strategically valuable.

Single armed merchantmen made the trans-Atlantic passage, but by 1537, Spain organized a convoy system so that merchant ships laden with cargos of gold, silver, and pearls would sail together under the protection of armed vessels to ensure a safe passage back to Spain. Still, treacherous reefs and hurricanes claimed many Spanish

treasure ships over the course of three centuries. Archaeologists have investigated Spanish merchantmen, including ships of the 1554 Fleet excavated by the Texas Antiquities Committee off Padre Island, Texas, the *Cayo Nuevo Wreck* documented by a joint INA/INAH project in the Gulf of Mexico, the 1559 Emanuel Point Shipwreck investigated by the Florida Bureau of Historical Research, Division of Historical Resources and University of West Florida off Pensacola (Smith 2018), the seventeenth-century Rincón Astrolabe Wreck in Puerto Rico, and the 1766 *Nuevo Constante*, investigated offshore by the State of Louisiana, but the majority of sites found have been salvaged by treasure hunters whose ethics regarding historical resources are not consistent with those of scientific archaeology. Among shipwrecks worked in cooperation with salvors are names such as *San Pedro* and *San Antonio* off Bermuda, *Nuestra Señora de Atocha* in the Florida Keys, *Nuestra Señora de la Pura y Limpia Concepción* (1641) on the Silver Bank of Hispaniola, and *Nuestra Señora de Guadalupe* and *Conde de Tolosa* (1724) off the northeast coast of Hispaniola.

Although treasure hunters compromised vessels of the 1715 Spanish Plate Fleet, discovered off the east coast of Florida, archaeologists investigated the *Urca de Lima*; in 1987, Florida designated the site as Florida's first Underwater Archaeological Preserve. Salvors also impacted the remains of the 1733 Spanish Plate Fleet that wrecked in the Florida Keys, although State of Florida archaeologists are undertaking scientific studies on a number of these vessels. In the Cayman Islands, archaeologists identified a site thought to be the remains of the inbound *San Miguel*, lost in 1730. In 1996, East Carolina University began a survey of the waters of Anguilla, which included assessment of two 1772 inbound Spanish merchantmen, *El Buen Consejo* and *Jesús, María y José*, at the invitation of the Historic Wrecks Advisory Committee; they produced a map and site analysis for the government. In Jamaica, INA assisted the government in the 1980s in surveys on the Pedro Banks for early shipwreck sites. Remoteness, complicated logistics, and nominal funding, however, discourage scientific work on these sites. In Puerto Rico, archaeologists have documented the Cerro Gordo sites in Vega Alta – a Spanish shipyard of the seventeenth to nineteenth centuries.

England, France, and the Netherlands challenged Spain's monopoly in the sixteenth and seventeenth centuries through official and entrepreneurial voyages; the Dutch created a wide commercial network, while the English and French began to settle the eastern Caribbean by the early 1600s. Meanwhile, Spanish colonies illicitly imported European products and African slaves from passing foreign merchant ships. In the Dominican Republic, the Pan-American Institute of Maritime Archaeology excavated a seventeenth-century interloper into the Spanish colonies. The investigators believe that the ship, known as the Monti Christi Shipwreck, was *en route* from Europe to North America, via the Caribbean when it wrecked. It appears to be an English-built merchantman carrying a Dutch cargo of clay tobacco pipes from Amsterdam. It wrecked between 1652 and1656, off the north coast of Hispaniola. French Louis XIV-period shipwrecks, lost during a 1677 battle with the Dutch in the Eastern Caribbean, were discovered during harbor-dredging activities in Tobago. In response, Trinidad and Tobago enacted legislation, based on the United Kingdom's Protection of Wrecks Act (1994), to safeguard these sites.

England and France established permanent settlements in the western Caribbean during the seventeenth century. In 1655, England seized Jamaica from Spain, while Spain eventually recognized the English claim in 1670, by the Treaty of Madrid. In 1655, France took Tortuga and progressively occupied all of St. Domingue (the western third of Hispaniola), but it was not until the 1697 Treaty of Ryswick that Spain recognized the French claim. It was an era of pirate and privateer exploits. In 1979, INA investigated the *Turtle Wreck*, an English turtle-fishing vessel likely burned in 1670 by Spanish privateer, Manuel Rivero Pardal in Little Cayman, and the Duck Pond Careenage used for overhauling vessels for at least three centuries in the Cayman Islands. In 2007, pirate Captain William Kidd's ship *Quedagh Merchant* was discovered in the Dominican Republic by a team from

Indiana University; lost in 1699, this shipwreck was scientifically investigated under direction of Frederick H. Hanselmann, and artifacts conserved in cooperation with Dominican Republic institutions; the site is now interpreted for the diving and snorkeling public, with plans underway to create a land-based exhibit (Hanselmann 2019). The Cayman Islands National Museum (CINM) test excavated a turtle-fishing encampment dating to about 1700 on the north coast of Grand Cayman, and excavated an early historic step-well on the island's western waterfront. They have found clues to HMS *Jamaica*, a British sloop on patrol for pirates when it wrecked in 1715 entering the great North Sound.

A catastrophic earthquake hit the thriving English colonial city of Port Royal, Jamaica, in 1692, causing much of it to subside into the liquefied sand of Kingston Harbour. Edwin Link and the National Geographic Society carried out underwater excavations in the 1950s, resulting in a pre-1692 map of Port Royal, while Robert Marx excavated caches of artifacts in the 1960s. Philip Mayes began terrestrial excavations in 1969. Texas A&M University and INA, under the direction of Donny Hamilton, and in association with the Jamaica National Heritage Trust (JNHT) conducted the first scientific underwater archaeological excavations. Hamilton led field schools from 1981 to 1990 in excavations of eight buildings and a ship that crashed into one building during the earthquake, training at the same time, Jamaica's first underwater archaeologist, Dorrick Gray, who subsequently served as Technical Director of Archaeology at the JNHT. Much of Port Royal remains in situ, and as such represents a time-capsule of seventeenth-century life. The Jamaican government is seeking World Heritage status for Port Royal; it is considering management options, and issues of preservation, research, conservation, and disposition of artifacts.

Britain and France dominated control of the Caribbean during the eighteenth century, protecting their colonies and lucrative sugar trade through naval power. They were opponents during a series of wars, with Spain and the Netherlands inconsistently allied with one or the other country: the War of Spanish Succession (1702–1713), the Seven Years War (1756–1763), the American War of Independence (1775–1783), the French Revolutionary Wars (1792–1802), and the Napoleonic Wars (1803–1815). Not surprisingly, a great number of merchantmen and warships were lost in the eighteenth-century Caribbean. Archaeologists discovered at least six eighteenth-century merchant ships in St. Ann's Bay, Jamaica; Greg Cook and a team from INA/JNHT investigated one British sloop, the Reader's Point Wreck, in the 1990s.

The French islands of Martinique and Guadeloupe compiled an online inventory of at least 73 UCH sites. Among the 19 identified sites are *Notre Dame De Bonne Espérance* (1687), HMS *Raisonable* (1762), and *Le Cygne* (1808). In 2019 Jean-Sébastien Guibert, Max Guérout, Marc Guillarme, and others published a very useful summary of colonial period (seventeenth to nineteenth century) maritime archaeological projects undertaken in the French Antilles between 1980 and the present, in the International Journal of Nautical Archaeology (Guilbert et al. 2019). Their overview includes coastal plantations, ports, and micro-islets, as well as shipwrecks related to commercial, naval, and cabotage use. They relate that the nature and distribution of sites provides information on maritime routes and traffic, trade, and conflicts, as well as environmental risks specific to the Antilles in the Colonial period. There is critical capacity building underway presently in Martinique and Guadeloupe.

In Saint Kitts and Nevis, the Nevis Maritime Archaeological Group, composed of local and international members, began conducting research in 2011 on HMS Solebay, lost on 25 January 1782 during the Battle of Frigate Bay. Established in 1979, the Dominican Republic's Comisión de Rescate Arqueológico Submarino conducted excavations in cooperation with commercial interests on the French warship *Scipión* (1782), and the French ships *Diómedes* and *Imperial* (1806); the *Museo de las Reales Atarazanas*, the *Museo de Arqueología Submarina del Faro a Colón*, and the *Museo de las Casas Reales* display artifacts from these shipwrecks.

In the 1990s, Margaret E. Leshikar-Denton, working with Texas A&M University and the

CINM, investigated the 1794 Wreck of the Ten Sail: HMS *Convert* and nine ships of her merchant convoy lost together on the East End reefs of Grand Cayman during the French Revolutionary Wars. The *Convert* was a captured French-built frigate, formerly called *l'Inconstante*, which retained her original French ordnance. The CINM's special two-hundredth anniversary exhibition commemorated the historical event in 1994, at which time Queen Elizabeth II visited the exhibition; it is being featured again in a new publication (Leshikar-Denton 2020). The Saint Maarten National Heritage Foundation, the Saint Maarten Department of Planning and Environment, and Maritime Archaeology and Research investigated HMS *Proselyte*, the captured Dutch frigate *Jason*, in 1994–95; the ship was lost in 1801. In the 1980s, the Archaeological and Anthropological Institute of the Netherlands Antilles (AAINA) investigated the Dutch frigate *Alphen* which exploded and sank in 1778 in Santa Anna Bay, Curacao; AAINA also recorded the SS *Mediator*, lost in 1884 in Willemstad Harbor. In cooperation with the Maritime Archaeological and Historical Society (MAHS), AAINA surveyed the historical anchorage adjacent to Fort Orange and Kralendijk, the population center in Bonaire, and identified the Dutch warship *Sirene*, lost in 1831. In Saint Vincent and the Grenadines, with the cooperation of the Government of Saint Vincent and the Organization of American States, a joint team of Florida State University and Institute of Maritime History researchers and students carried out a project in Kingstown Harbor on a late eighteenth-century shipwreck in 1997–1998. In Puerto Rico, archaeologists have recorded an eighteenth-century English warship wrecked on the Laurel Reefs of La Parguera, Lajas.

A significant part of Caribbean history is reflected in the search for the slave ship *Trouvadore*, a Spanish ship that was lost in 1841 with a human cargo of 193 people. Intended for slavery in Cuba, the Africans instead found freedom in the Turks and Caicos Islands and thereby influenced the cultural future of that country. In 2008, Ships of Discovery investigated remains of a vessel believed to be *Trouvadore* and also located remains of the US Navy brig *Chippewa*, lost in 1816 while patrolling the Caribbean on a mission to counter the African slave trade and piracy.

The nineteenth century brought the end of the Age of Sail and the flourishing of the Age of Steam. In Puerto Rico, the Underwater Archaeology Office of the *Consejo para la Conservación y Estudio de Sitios y Recursos Arqueológicos Subacuáticos* recorded the Spanish steamships *Alicante* wrecked in 1881 and *Antonio López* lost in 1898 during the Spanish-American War. Archaeologists have also assessed Buoy 4 in San Juan to investigate the *Manuela* and *Cristobal Colon*, also casualties during the Spanish-American War. In Anguilla, Lillian Azevedo and a team from the University of Southampton have recorded early historic wrecks and a nineteenth-century shipwreck.

Even twentieth-century wrecks are subjects of research and eco-tourism in the Caribbean. Bert Ho and a team from Florida State University assisted the CINM in documentation of the Norwegian-flagged *Glamis*, lost in 1913, providing the foundation to create a future shipwreck preserve on the robust shipwreck site in the Cayman Islands. *Glamis* had been built in Dundee, Scotland, in 1876. *Geneva Kathleen*, a three-masted schooner wrecked in 1930 loaded with lumber, was documented by Ball State University, also in the Cayman Islands. In Puerto Rico, archaeologists have documented World War II era vessels, including a PT boat in Desecheo Island, and two aircraft – a B-29 in Aguadilla and a PBY Catalina flying boat in La Parguera – for the US Navy.

Meaning to Descendent Communities

An important theme in the Caribbean is the meaning of maritime and underwater cultural heritage to descendant communities. In the Turks and Caicos Islands, the case study of a descendant African community whose ancestors escaped intended slavery in Cuba, through wrecking in the Spanish ship *Trouvadore*, is remarkable; it provides the opportunity for people to learn more about themselves, where they came from and how they have survived. Maritime themes like shipwrecks, historical shipbuilding of

schooners and catboats, place-names, and hurricane caves, among other topics, are important to the people of the Cayman Islands; thus, involving all levels of society in the Maritime Heritage Trail engages people in their heritage. In every country, there are unique examples that can link communities to their heritage and this communication provides value and self-esteem in return to living people.

International Perspectives and Future Directions

Since the mid-twentieth century, the world's underwater cultural heritage has become more and more accessible, and has become an easier target for exploitation. At the same time, professional underwater and maritime archaeological research has experienced a profound period of growth. It is also becoming clear that UCH has value not only to scientific research, but also has a role to play in cultural, educational, and economic terms. Countries, including those in the Caribbean, are discovering innovative ways to manage and preserve maritime and underwater cultural heritage sites, and to promote them locally, regionally, and internationally.

Today is a good day for maritime archaeology in the Caribbean – today we have tools in our kit that have been created through negotiations among countries of the world, including those from Latin America and the Caribbean. Using the 1996 ICOMOS Charter and the 2001 UNESCO Convention, we can speak the same language in attributing value to UCH and providing for its protection, management, interpretation, and public access and benefit – these documents can guide us in "best practice" and in establishing compatible national legislation. As a brilliant Argentinian lawyer put it during the Paris negotiations, the magic word is "cooperation" among stakeholders – and so, countries, governments, professionals, and the public who communicate and assist one another through local, regional, and international agreements and through sharing technical and professional resources can shape a positive future.

Caribbean Prehistoric Archaeology

Michele H. Hayward and Michael A. Cinquino
Panamerican Consultants, Inc., Buffalo, NY, USA

Introduction

Caribbean prehistoric research is characterized by:

- A history of robust amateur archaeological contributions to investigations and organizational (government, professional, cultural) structures.

- Increased explicit reference in the literature to theoretical approaches and use of formal methodologies, as well as expanding research fields (starch grain analysis, household studies) that nonetheless build upon a basis of discipline-wide accepted sound practices and concepts, in addition to regional inventive formulations and applications.
- A legacy of US, English, Dutch, Danish, French, and Spanish past and present administration that provides for both a positive and negative research environment. For instance, while diverse approaches and methods can stimulate methodological and theoretical advancement, they can also limit inter-region comparisons and higher-order theory building.
- Diverse laws and regulations regarding the preservation, access, and investigative platforms – amateur, academic, governmental, and private – of sites due to the mix of former-colonial-now-independent and still-associated-to-colonial-origin nations in the region.
- Variability in research results from surveys to excavations, to syntheses, as well as to their availability (different languages, publishing outlets, and institutional access protocols), leaving certain islands, sites, and research themes more studied than others.
- Growing utilization of modern communication forms including web sites, online materials, and digitized data, in addition to standard publication and conference venues to maximize the flow of information for the Caribbean and wider archaeological communities.
- The use of European accounts of native societies at or near contact and ethnographies of culturally cognate northern South American peoples along with archaeological materials to reconstruct the area's past lifeways.

Physical Setting

The following unfolding of Caribbean prehistory takes place within a geographically and culturally defined region that differs according to particular research objectives. The broad cultural delineation encompasses the Caribbean Sea islands, as well as the North, Central, and South American coastal zones (Fig. 1). The West Indian archipelago arcs broadly outward from the Venezuelan coast of South America to the southeast tip of North America and the Yucatan Peninsula of Mexico in Central America, extending over a lineal area of some 2500 km. These islands display a wide range of landforms, geologic processes, natural resources, and climatic regimes that are commonly differentiated into four physiographic subregions: the Greater Antilles and the Virgin Islands, the Lesser Antilles plus Trinidad and Tobago, the Bahamian grouping, and the southern Caribbean Islands off the coast of Venezuela (Keegan and Hofman 2017: 2–3; Hayward et al. 2009a: 3).

The Greater Antilles comprises Cuba, Jamaica, Hispaniola (modern states of Haiti and the Dominican Republic), and Puerto Rico, plus various smaller in size nearby islands. They account for 88% of the landmass with a topography dominated by mountains, valleys, and coastal plains derived from limestone, sedimentary, and metamorphic rocks of volcanic substrate. The Virgin Islands lie eastward of Puerto Rico combining a number of small islands under US (St. Croix, St. Thomas, St. John) and UK (Tortola, Virgin Gorda, Anegada) administrative jurisdictions. Volcanic rock predominates on the US Virgin Islands with hilly terrain, minimal-level portions, and rather thin coasts that rest on a shallow island shelf connected to Puerto Rico. Low limestone surfaces characterize the British islands, where the combined Virgins make up an additional 1% of the Caribbean landmass (Keegan and Hofman 2017: 5–6; Hayward et al. 2009a: 3, 5).

The islands of Sombrero and Anguilla in the north to Grenada off the coast of Venezuela plus Barbados comprise the Lesser Antilles. Originating from volcanic and limestone bases, the islands present a double arc configuration of inner high volcanic and outer lower limestone landforms with the distinction evident north of Dominica. The grouping is traditionally further divided into the northern Leeward Islands and the southern Windwards with the dividing line normally between Guadeloupe and Dominica. Island sizes

Caribbean Prehistoric Archaeology, Fig. 1 Map of the Caribbean (Hayward et al. 2009a: Fig. 1.1)

are notably less extensive than those of the Greater Antilles accounting for 3% of the total landmass (Bright 2011: 30–31; Keegan and Hofman 2017: 5, 197; Hayward et al. 2009a: 5).

Trinidad and Tobago, today just off the coast of Venezuela, broke off at different times from South America at the end of the Holocene around 7000 BC. Their continental origin is displayed in the islands' closer biological and physical relationships with northeastern South America than their insular neighbors to the north. Trinidad is distinguished by mountain ranges, low hills, poorly drained lowlands, and coasts atop sedimentary, limestone, and volcanic substrates. Most of Tobago consists of a central highland ridge of primarily metamorphic and volcanic rock origin, ringed by a shoreline. Both these islands make up 2% of the region's extent (Keegan and Hofman 2017: 5; Hayward et al. 2009a: 5).

The Bahamian archipelago encompasses 35 small coral limestone islands of low relief, normally less than 30 m high. They, along with some 3000 cays (islands) of even lesser landmass, extend over 1000 km from near the southeast coast of Florida to the north of Hispaniola and Cuba. Their 5% of the area is governed by the independent Commonwealth of the Bahamas and the British Oversees Territory of the Turks and Caicos Islands. Although these landforms are located in the southern North Atlantic, they are included in the area due to their similarities in history, climate, and biota with the rest of the Caribbean (Keegan and Hofman 2017: 6, 170; Hayward et al. 2009a: 5).

Roughly parallel to the Venezuelan coast, and generally within 50 km, lies a line of islands from Aruba to Margarita termed the Southern Caribbean Region. Aruba, Bonaire, and Curaçao being former Dutch colonies retain a political association with the Kingdom of the Netherlands, while Margarita and the remaining islands fall under Venezuelan authority. Accounting for less than 1% of the land extent, the islands derive from volcanic rocks yet with normally low-lying limestone surface forms. They all, like Trinidad and Tobago, reflect the flora and fauna, as well as

material culture of the mainland (Keegan and Hofman 2017: 4–5; Hayward et al. 2009a: 5–6).

Environmental Considerations

Early entrants into this physical setting would have been presented with certain challenges to settlement, balanced by inviting and sustainable resource opportunities. Regarding the physical layout (see Fig. 1), with limited exceptions, all the islands are visible from one another. Continental-to-island chain visibility gaps involve the Yucatan and Florida Straits where Cuba cannot be seen from the Yucatan Peninsula and neither the Greater Antilles nor the Bahamas can be seen from Florida over distances of 200, 185, and 100 km, respectively (Callaghan 2013: 285–286; Torres and Rodríguez Ramos 2008). Modeled extended or intervisibility ranges add two intraisland gaps: the 65 km Anegada passage between the northernmost Leeward and Virgin Islands as well as the waterways delineating Cuba and Hispaniola from the Bahamas ranging from some 100 to 200 km (Torres and Rodríguez Ramos 2008).

The Caribbean's pleasantly considered tropical regime encompasses sunny days and warm waters along with fairly dependable cooling trade winds. Seasonally, rainfall is divided into a rainy period from May to October and a dry one from November to April. Factors affecting annual precipitation include altitude and island topography. Rainfall on some of the low Bahamian islands registers less than 29 in. per year, while the mountainous rainforest on Puerto Rico receives 120 in. The interaction of the trade winds and island landforms results in greater rainfall on the windward or north and east sections and lesser amounts on the leeward or south and west portions. While the region's climatic may not have changed significantly from prehistoric times, alternating drier and wetter periods are indicated from core samples (Bright 2011: 33; Cooper 2013: 53; Keegan and Hofman 2017: 29; Wilson 2007: 11–13).

Sea levels, both relative and absolute, have also varied during the human occupation of the region. Climatic changes along with such factors as plate tectonics (subsidence or uplifting) combined to affect a lower sea level (figures vary in literature) than today's around 7000 BP or some thousand years before initial human entry. Such lower levels may have increased the total landmass by 15%. Subsequently, levels then rose to near the modern level by 5000 BP and have been slowly falling since. Trinidad becomes completely separated from the South American mainland by roughly 6200 BP and from Tobago even earlier at the beginning of the Holocene 10,000 years ago. To these longer-term climatic-related variations must be added, then as now, periodic occurrences of hurricanes and volcanic eruptions (Bright 2011: 33–35; Cooper 2013: 51–55; Cooper and Boothroyd 2011).

Shifts in duration of rainy and dry seasons, as well as changing island sizes, biotopes, and navigation routes, along with episodes of sudden high winds, heavy precipitation, storm surges, lava flows, fires, and toxic gases would have affected the region's availability of freshwater, food resources, and settlement integrity (via destruction, changing resource base, or submergence). All of these conditions would have distressed both agricultural and nonagricultural practicing societies. While systematic macro- to microscale human-environmental relationships remain underdeveloped, archaeological and ethnohistorical data provide evidence for these ecological instabilities and their cultural responses. Coastal and inland flooding (storms, hurricanes), draughts, storm-deposited bands of sterile sand, and volcanic deposit events are indicated, as are compensating measures including caves for temporary shelter, wind-resistant structures, settlement relocation on the same or different islands, modifying subsistence strategies, and posited changes in sociopolitical systems (Bright 2011: 33–36; Cooper 2013; Cooper and Boothroyd 2011).

Environmental unpredictability was offset in the region with a great diversity in edible and useable plant and animal resources that were, of critical import to their exploitation, unevenly distributed across the islands. Many of the biota would have been familiar having been derived from Central and South America though in contrast characterized by lower species diversity,

especially that of terrestrial animals, and the presence of abundant aquatic resources. Available terrestrial species included giant ground sloths, a giant flightless owl, the Greater Antillean spiny rat, the hutia (medium-sized rodent), tortoises, and shrew-like insectivores. Manatees, whale and dolphin species, and marine turtles as well as fishes like sharks and tuna accounted for deeper or open water resources. Freshwater turtles, iguanas, crocodiles, numerous fishes, crabs, and shellfish could be found in rivers, estuaries, shorelines, offshore banks, and reefs. Various birds were also present including ducks, parrots, pigeons, and frigates (Bright 2011: 31–33; Keegan and Hofman 2017: 29–30, 197).

A range of forest types from tropical rainforests to dry stands provided opportunities for the exploitation of fruit-bearing trees such as guava. The calabash, lignum vitae, and silk cotton trees were available for their gourds, wood, and bark/fiber, respectively. On land, suitable soils and landforms could be found on the well-drained high ground back from coastal embayments, as well as small to large river valleys. The latter were chiefly restricted to the Greater Antilles though counterbalanced in the Lesser Antilles by productive offshore shallow shelves and banks sometimes larger than their connected landmasses (Bright 2011: 33; Wilson 2007: 9, 14–15).

Once in the region, human occupation or domestication of the islandscape had profound environmental effects. Faunal groups quickly went extinct or nearly so, particularly the Pleistocene-ending mammalian species like the sloths, due to hunting, climatic changes, habitat destruction, or their combination. Plants and animals from the continent and within the region were introduced such as manioc, sweet potato, peppers, tobacco, monkeys, dogs, and guinea pigs from the mainland, while the hutia apparently native to Hispaniola was transported early on to Puerto Rico and the Virgin Islands. Intensive agricultural practices, added to large-scale forest clearing, led in many areas to replacement of primary by secondary vegetation, soil erosion, and increased sedimentation (Bright: 32, 36–37; Keegan and Hofman 2017: 29–30, 197–198, 172).

Terminology and Chronology

Caribbean prehistory involves a complex interplay between the physical environment of islandscapes, seaways, and continental zones with the social one of different groups, languages, and material cultures. A number of regional to local frameworks have been devised that relate population movements and cultural changes through time. The nomenclature for contact and classification of prehistoric societies is varied and overlapping and can be confusing. Commonly encountered terms and their understandings are detailed in Table 1. The Taíno, for instance, refer to diverse through culturally related groups in the northern Antilles that formerly were referred to as Arawaks. The term Taíno was adapted to distinguish Caribbean from northeast South American contact period groups, in addition to its reference as a language. Further both terms are also used for precontact societies as depicted in Figs. 2 and 3: Pre-Arawak for the Lithic/Archaic Age; Arawak and Pre-Taíno/Taíno for the Ceramic Period.

A considerable amount of research effort has been directed toward devising spatial-temporal frameworks for prehistoric populations that reflect diverse theoretical perspectives, as well as levels of inclusion from local to regional. The fundamental Caribbean-wide model is that of Irving Rouse who began developing his scheme early in the history of formal Caribbean research around the 1940s. He and other investigators have revised the framework over the years with the latest full version presented in his 1992 publication *The Taínos*. Four broad Ages are recognized: Lithic, Archaic, Ceramic, and Historic or Contact.

Rouse's model (under the cultural-historical paradigm) represents a hierarchical ordering of cultural integration at five levels of increasing inclusion and decreasing variability. The most inclusive and least variable level is that of the foregoing four ages followed by series, subseries, styles, and wares. A style represents a similar set of core attributes from multiple assemblages, while a ware may possess certain attributes that completely or partially characterize a style. For instance, zone-incised crosshatched wares are

Caribbean Prehistoric Archaeology, Table 1 Terminology for precontact Caribbean societies

Term	Description	Sources
Guanahatabey or Ciboney	Frequently refers to hunter-gatherer-collector populations in western Cuba and possibly Hispaniola (their survival to contact under investigation) – can also refer to specific and generalized such groups or later Taíno populations in central Cuba	Reid (2014a: 103–105), Rodríguez Ramos (2010: 51–52), and Wilson (2007: 33, 145–146)
Taíno(s)	Diverse (sociopolitical, linguistic, ethnic) though culturally related societies in the northern Antilles. Further subdivided based on geography and inferred level of cultural development: Classic Taíno in eastern Cuba, Hispaniola, and Puerto Rico; Western Taíno of central Cuba and Jamaica; Eastern Taíno the Virgin Islands and northern Lesser Antilles; Lucayan Taíno of the Bahamas; the later three category populations considered less developed – Taíno and Pre-Taíno also used to designate Ceramic Period precontact peoples	Keegan and Hofman (2017: 13–14), Peterson et al. (2004: 18–19), and Reid (2014b)
Arawak	Formerly used interchangeably with Taíno; Arawak also refers to contact period groups from northeast South America that were culturally distinct from those of the Antilles, with the word Taíno adopted to clarify the distinction; Arawak or now Lokono language distinct from Taíno and Island Carib speech but all within same language family – also use of the terms pre-Arawak and Arawak to label Lithic/Archaic and Ceramic Period prehistoric groups	Reid (2014b)
Island Carib or Carib	Groups who occupied the Lesser Antilles from around Guadeloupe to northern Trinidad at contact	Keegan and Hofman (2017: 14–15), Peterson et al. (2004: 19–20), and Reid (2014c)
Igneri	No consistent use of the term; frequently refers to specific groups or languages in the Lesser Antilles; also used to define certain other precontact groups	Granberry (2013: 64–67), Keegan and Hofman (2017: 14), and Peterson et al. (2004: 20)

found in Hacienda Grande styles, along with the more frequent white-on-red painted wares, but are exclusive to Huecan styles.

As elaborated over time, these styles have been dominated by ceramic attributes and secondarily with characteristics from other artifact classes like lithics and shell. Rouse has considered the ceramic styles to largely equate with the peoples that manufactured the pottery who occupy discrete temporal units and geographic locations. Series are groups of styles, also non-overlapping-in-time-and-space that derive from a common culture affiliation defined by basic or critical attributes. The subseries is intermediate between the style and series covering still more limited in extent related styles and inferred associated peoples.

Graphically, Rouse's classification categories are presented as a matrix with calendric dates along the vertical axis and geographic areas along the horizontal in Figs. 2 and 3. The time frame is derived from cross-dated assemblages and a still limited through growing corpus of radiocarbon dates. Relative positioning of the categories reflects stratigraphic sequencing, while areal extents cover individual islands and inter-island water passages. His 1992 matrices or Figs. 14 and 15 for the Greater and Lesser Antilles, plus adjacent northern South America, are redrawn, expanded in areal extent, and updated from other sources that simplify the visual presentation of his categories. Changes include grouping together islands with the same categorization and conflating the water passage distinctions. The latter remain relevant since at certain times and places in the precontact Caribbean, material cultures were more alike from island portions facing a common waterway than even from the same

Caribbean Prehistoric Archaeology, Fig. 2 General cultural chronology of the Greater Antilles (Berman et al. 2013; Rodríguez Ramos 2010; Rouse 1992: 52 Fig. 14). (After Hayward et al. (2009a: Fig. 1.2))

Caribbean Prehistoric Archaeology, Fig. 3 General cultural chronology of the Lesser Antilles (Boomert 2000;54, 128 Figs. 7 and 15, respectively, and personal communication 2007; Haviser 2001: 18; Newsom and Wing 2004: 61; Peterson et al. 2004:32 Fig. 1; Rouse 1992: 53 Fig. 15). (After Hayward et al. (2009a: Fig. 1.3))

island. Columns for the series and subseries are provided, with all such divisions detailed in Tables 2a, 2b, and 2c. By convention, the series labels end in "oid" and the subseries in "an," as in the Elenan subseries of the Ostionoid series.

The Lithic and Archaic Age Casimiroid peoples in the northern and Ortoiroid groups in the southern Antilles begin to settle the region as exploiters of raw materials, animal, plant, and marine resources around 6000 BC. Their material culture primarily consists of worked stone, shell, and bone artifacts with evidence of ceramic production, recurrent settlements, and plant management. Around 500 BC, new in-migrating societies bring with them such cultural traits as full-scale pottery production, settled village life, and horticulture. These Early Ceramic or Saladoid societies are found throughout the Lesser Antilles and the northeast Greater Antilles. Subsequent insular as well as insular-continental cultural dynamics

Discrepancies in dating of ceramic categories among the sources

are marked by the increasing differentiation of peoples into various Late Ceramic Ostionoid groups in the Greater Antilles and Troumassoid, Suazoid, Mayoid, and Cayo populations in the Lesser Antilles (Rouse 1992; for discussion of Rouse's model, see especially Curet 2005: 11–15, 57; Keegan and Hofman 2017: 16–17; Peterson et al. 2004: 21–22; Krause 2016).

Also developed over the years is the alternative classification system of (Chanlatte Baik and Narganes Storde 1983; Chanlatte Baik 2013) involving three developmental phases within the region (Fig. 4). Phase I comprises interacting Archaic and certain ceramic-producing groups in northern South America that serve as parent populations for in-migrating Archaic groups. They are followed by two separate groups of farmer-potters or Agroalfareros I from northwest and northeast South America. In Phase II these three groups adjust to their environment, interact, yet maintain their individual cultural identities now transformed from continental to insular Archaic, Huecoid Agroalfareros I and Saladoid Agroalfareros II. Phase III further interactions yield the distinct Ostionoids or Agroalfareros III around AD 600 that subdivide into the Elenan and other Late Ceramic Rouse-defined subseries terminating with the Agroalfareros IV or contact period Taíno groups.

Marxist theory has also served as an organizing framework for the definition and understanding of past Amerindian societies in the Caribbean. Cubans, for instance, have elaborated a varied taxonomy including two interrelated systems. One focuses on ceramic and agricultural differentiation – *pre-agroalfareros* (preagroceramicists), *protoagricola* (protoagriculuralists), and *agroalfarero* (agricultural-ceramicists). The second one emphasizes socioeconomic development where an economy of appropriation associated with hunting, fishing, and collecting societies, as well as protoagriculturalists, gives way to an economy of food production associated with horticulturalists (Cooper 2010: 86; Keegan and Hofman 2017: 152; Ulloa Hung and Valcárcel Rojas 2013; Wilson 2007: 21).

Regarding current conceptual frameworks, the following observations can be made:

- A mix of traditional – Marxism and Structuralism – and more recent theoretical approaches, cognitive and landscape archaeology.
- The incorporation of newer orientations and technologies – GIS and computer simulations – into research projects that nonetheless continue to focus on long-studied questions of migration, culture history, and societal developmental processes.
- The realization that an island-human dynamic differs from a continental one.

Caribbean Prehistoric Archaeology, Fig. 4 Alternative cultural chronology of the Caribbean: Agroalfarero or Famer/Potter Sequence. (After Chanlatte Batik and Narganes Storde (1983: Fig. 1))

- A focus regardless of any particular theoretical orientation on the diversity or plurality of societies, not their homogeneity.
- A related-to-the-diversity-focus involves the incorporation of cultural contact situations including transculturation, assimilation, and displacement.
- A renewed emphasis on anthropological archaeology where the archaeological record is seen as resulting from a series of complex negotiated social relationships at multiple levels of organization involving a range of items from material goods to ideas.

Early Occupation of the Caribbean

Initial entry into the area takes place against a backdrop of long-settled continental zones with reasons for movement into the expansive island environment remaining unclear. Motives look to have been more related to positive than negative factors such as resource depletion or major socio-political conflicts. The allure of water-oriented populations to an assumed similar-enough setting, in addition to the potential for valued plant, animal, and material resources, may have served as attractive reasons. At around the same time as the first peoples were entering into the region, 4000–3000 BC, mainland societies were engaged in long-distance interaction spheres involving various items and in particular lithic raw materials. The search for desired items would have led, for instance, to the discovery of the region's abundant and high-quality lithics providing for both inter-regional and eventually intra-regional trading prospects (Rodríguez Ramos 2010: 87, 2013: 131–132; Wilson 2007: 3–4).

Dates from select sites for this long Lithic/Archaic occupational phase are presented in Table 3. The earliest ones for the Greater Antilles involve several Cuban sites with BP ranges for five sites of from 5140 to 4000 with their calibrated BP dates (lower ranges) yielding older results 6300–4900. The two earliest sites are those of Cueva de la Lechuza with a calibrated BP variance of 6298–5746 and Levisa I with 6288–5584. Angostura in Puerto Rico registers an older BP assay of 5960 ± 250 with a calibrated BC date of 4900. The Vignier phases II and III in Haiti present comparable BP dates of 5580 ± 80 and 5270 ± 100, respectively. In the Lesser Antilles, Trinidad appears to have had a Paleo-Indian component based on the presence of a stemmed projectile point and a plano-convex scraper; however this possible occupation and the oldest sites occur when the island was still attached to northeast Venezuela or transitioning to island status. Banwari Trace dates involve the identification of three phases beginning with 7800–7900, 6900–7400, and finally 5500–6200, all cal. BP values. St. John has various reported dates including a seven-value range from cal. BC 5840–5720 to 3590–3370 with the corresponding cal. BP set from 7790–7670 to 5460–5300 (Boomert 2000: 49, 2013: 142; Pagán Jiménez et al. 2015: 233 Table 1; Tankersley et al. 2018: 693).

Despite these early dates, major settlement of the region likely begins later and especially between 4500 and 2500 BP. Earlier phase sites include Maruca and Paseo del Indio in Puerto Rico, Jolly Beach in Antigua, Sugar Factory Pier in St. Kitts, and Etang Rouge in St. Martin. Later period increases involve Canímar Abajo on Cuba, Barrera-Mordán on Hispaniola, Krum Bay on St. Thomas (US Virgin Islands), Plum Piece on Saba, the River Site on Barbuda, Whitehead's Bluff on Anguilla, Norman's Estate on St. Martin, Heywoods on Barbados, and Milford I on Tobago. It should be added that still older sites may be located along drowned shorelines due to rising sea levels, buried under volcanic ash or alluvial deposits, or in other archaeological contexts (Table 3; Cooper and Boothroyd 2011; Rodríguez Ramos 2013: 127–128).

Although Lithic/Archaic site distribution is widespread over the 1500 km island chain, it is uneven. The larger landforms of Jamaica and the Bahamian archipelago in the Greater Antilles were never permanently settled, as well as it seems most of the southern Lesser Antilles. Apart from Trinidad, Barbados and Tobago, and Le Godinot and Boutbois on Martinique (with questioned Lithic/Archaic status), plus evidence from core samples of possible human-related fires on Martinique and Grenada, no other such sites

Sources for a site's multiple date sequences are either given under the dating column separated by lines or under the sources column

have been located. This lack of discovery may be due to site survey deficiencies, or their burial and erasure from the various environmental destabilization conditions already noted (Bright 2011: 38; Keegan and Hofman 2017: 37, 170, 189, 200–201, 207).

The distribution is also uneven with regard to site concentrations. Significantly higher site numbers are recorded for Cuba (some 2000), Hispaniola (240 for Haiti alone), Antigua (43), and Trinidad (28), heavily overshadowing site numbers of just a few for the remaining islands (Boomert 2000: 54–55; Keegan and Hofman 2017: 119, 152, 200–202; Wilson 2007: 51). A pattern of early and then later dating phases and wide though unequal site distributions indicates that movement into the region was not one of gradual island-by-island occupation, but one of rather rapid direct movements across open waters, a process that over time went from exploring and identifying desirable resources and suitable settlement locations by a limited number of groups to increasingly settler populations willing and able to move into and around the new islandscape (Keegan and Hofman 2017: 55; Rodríguez Ramos 2013: 127; Wilson 2007: 27, 46–47).

Although direct archaeological evidence is limited, the proposed open water routes, as well as later insular travel, were accomplished via canoes, apparently sailless. Recovered watercraft remains comprise dugout canoes and paddles, where complete enough mirror those of present Arawak-speaking groups of the Venezuelan Upper Orinoco region. Ethnohistoric sources provide comment on the size and speed of canoes – different sizes depending on near-shore or long-distance travel that could accommodate up to 100 paddlers and speeds of 6 knots per hour – but lack details on long-distance seafaring capabilities. Nonetheless the available evidence suggests frequent use of canoes for a variety of purposes across a clearly marked seascape (Callaghan 2013: 284, 288; Keegan and Hofman 2017: 54–56, 183–184).

Movements of peoples, materials, and ideas into, out of, and around the Caribbean during the entire precontact period reflect intersecting sets of multiple continental and island origins via different strategies. Several continental donor regions for initial Lithic/Archaic Age groups have been advanced – the Southeastern United States, Central America, the Isthmo-Colombian area, and northeast South America – that ongoing research may as yet confirm one, all, or even other areas.

The case for a Southeastern United States and Cuba link rests on particular similarities in material culture, site types, and agricultural traditions, including (1) correspondences between the early Cuban microlithic traditions and the North American Western Lithic Co-Tradition; (2) the presence of shell gouges, bannerstones, and fiber-tempered pottery in both areas (the microlithic technology and pottery could also reflect later exchanges); (3) shell mound structural commonalities; and (4) comparable agricultural tradition components with plants like maize and zamia (small, stocky, fernlike plant) that even suggests their transference from the Caribbean to the southeast due to their very early presence rather than via a mainland route. Even with these correspondences, it has been argued that the material cultures as a whole are substantially different calling into question this migration vector (Keegan and Hofman 2017: 26–27, 169; Rodríguez Ramos 2013: 130–131).

Resemblances between the macroblade assemblages of Cuba and Hispaniola and those of Belize in particular have been used to argue for the Yucatan to Honduras area of Central America for initial colonizing groups. Specific examples involve a dagger-shaped form in both the Greater Antilles and Belize and so-called bicycle seat bifaces from Cuba that closely resemble shoe-shaped constricted axes in Belize. Physical proximity coupled with the absence of Lesser Antillean sites at this time and the presence of similarly dated blade technologies in both areas lend support for this point of origin. However, like the posited Southeastern United States region, it can again be argued that the lithic industries are dissimilar enough to eliminate the Yucatan region from consideration (Callaghan 2003; Keegan and Hofman 2017: 25–27; Rodríguez Ramos 2013: 129; Wilson 2007: 27–33).

The Isthmo-Colombian area, especially from Panama to northwest Venezuela, may have served

as direct donors of peoples along with an established cultivation system. Greater Antillean sites dated to the earliest occupation phases from Puerto Rico, for instance, demonstrate marked correspondences between island and mainland plant arrays, along with an associated tool kit for their processing. The plant suite involves maize, sweet potato, manioc, beans, and avocado with characteristic edge-ground cobbles and milling stones for their processing. The circumscription of this plant suite-lithic processing complex to the Isthmo-Colombian area, plus its lack in Mesoamerica and the southeastern United States, as well as seemingly from early northeastern South American and the southern Lesser Antilles contexts strengthen this area as a migration vector (Rodríguez Ramos 2010: 83–87; Rodríguez Ramos 2013: 156–158; Pagán Jiménez 2013: 395–396). Yet the more recent identification of such plant remains including maize and sweet potato from one site each in Trinidad and French Guiana suggests a still-unfolding complex interaction of plants, peoples, culinary traditions, dispersal patterns, and points of origin (Pagán Jiménez et al. 2015).

Settlement of Trinidad, Tobago, and Barbados most likely derives from northeast Venezuela perhaps during the Paleo-Indian period associated with the Joboid mainland culture, but with well-grounded evidence around 6000 cal. BC (see Table 3). One possible donor culture is the Alaka complex represented by a series of shell middens in northeast Guyana (Orinoco Delta region). Dating to 6000–4000 cal. BC, the initial phase of the complex shares such traits as ground stone tools and an informal lithic industry with Trinidadian sites. Tobago was next colonized likely from Trinidad around 3000–1000 BC with Barbados occupied about the same time, but more probably via a separate Venezuelan migration since its material culture is so distinctive. North of these islands, occupation remains a question for the southern Lesser Antilles (see above), while the northern section was apparently not colonized until later suggesting either a direct route from the mainland or westward from the Greater Antilles (Boomert 2013: 142; Keegan and Hofman 2017: 37–38, 200–201, 207–208; Rodríguez Ramos 2013: 130; Wilson 2007: 38–39, 43–45).

Specialized studies directed at the migration issue include computer simulations of mainland-to-island routes that take into account wind and current data using sailless canoes. The results suggest that the unintended chances of reaching the Greater Antilles are highest from northern South America, in particular western Venezuela and eastern Columbia, and lowest from Florida and the Yucatan Peninsula. Intentional voyages from the three mainland areas all have a high degree of success; however the latter two regions require a greater degree of seafaring skill making northern South America again more likely (Callaghan 2013:290–291).

Lithic/Archaic Age

Classification

Just as the initial entry of Lithic/Archaic Age peoples into the region remains an unresolved and ongoing issue, so too does their characterization. The traditional view of continental-modeled hunter-gatherer bands differentiated into two succeeding ages based on different technologies, Lithic with flaked stone tools and then Archaic with ground stone and shell artifacts, as well as their differentiation from the Ceramic Age – lack of pottery and cultivation practices – no longer holds. The emerging picture is one of diverse societies employing a mix of technological, settlement, and subsistence strategies to exploit a varied resource base. While this 5000-year period presents opportunities for newly drawn internal distinctions, no formal region-wide framework has been developed to replace existing ones. Current discussions normally acknowledge the problem of attempting to place groups within existing model categories or treat the periods as one; the latter option is followed here (see Keegan and Hofman 2017: 23–24; Rodríguez Ramos 2010: 50–53, 2013: 132–133 for classification issues).

The Lithic-Archaic Age distinction, considered to reflect a separate arrival of ground stone-making communities from northeast South up to the island chain as far as Puerto Rico, is now viewed as an equally early and complementary introduction (Keegan and Hofman 2017: 34–39;

Rouse 1992: 49–51, 62, 67–69; Wilson 2007: 37–38). Ground stone, shell, and flaked stone tools are found together at a number of sites across the chronological and geographical spectrum, as indicated in Table 3 (Keegan and Hofman 2017: 33, 208; Rodríguez Ramos 2010: 62). The distinction, nevertheless, is still relevant since it touches on Rouse's classification of these societies.

The first division as outlined in Table 2a (see also Figs. 2 and 3) is between the Casimiroid cultures of Cuba, Haiti, and the Dominican Republic and the Ortoiroid groups of Puerto Rico, the Virgin Islands, northern Lesser Antilles, and the Trinidad area. Puerto Rico and the Virgin Islands are included with the Ortoiroids based on the aforementioned assumed similar mainland origin and correspondences with assemblages southward. However now the distinction is more likely between the Trinidad area and the rest of the Antilles.

The Casimiroid series comprises three subseries, the first being the Lithic Age Casimiran from around 4000 BC to 2000 BC with three cultures in Cuba, Haiti, and the Dominican Republic. The succeeding two Archaic subseries run from 2000 BC to variable ending dates, the Redondan to AD 500/800 for the two complexes of eastern and central Cuba and AD 1500 or contact for these complexes in western Cuba, while the Courian complexes on Hispaniola end at AD 500. Early sites on Puerto Rico have largely been identified after Rouse's classification effort so the Lithic phase remains unclassified. The following Archaic Corosan subseries comprises three complexes, one each for Vieques (island off the east coast of Puerto Rico), Puerto Rico, and Krum Bay on St. Thomas, US Virgin Islands.

Boomert (2000: 54–55) relaying on Rouse's approach has classified Trinidad and Tobago into two subseries. The Banwarian from 6000 to 2500 BC contains three complexes on Trinidad and one on Tobago followed by the Ortoiran 1500–300 BC with the single complex confined to Trinidad. Lesser Antillean sites were poorly known with Rouse declining to formally classify them; however considering his criteria they would all be considered Ortoiroid. Keegan and Hofman (2017: 201) have recently proposed an alternative northern Lesser Antillean combined Lithic/Archaic Age classification: Early Archaic 3300–2600 BC, Middle Archaic 2600–800 BC, and Late Archaic 800 BC–AD 100. The possible two sites on Martinique and Heywoods on Barbados retain unclear regional associations, although Rouse did consider Le Godinot and Boutbois to be Ortoiroids (Rouse 1992: 63, 65).

Material Culture

The Lithic/Archaic material culture includes an array of flaked, use-ground (ground from use not intentional manufacture), and ground stone tools, alongside those of shell, bone, and coral. Certain patterns in flaked stone assemblages have been identified including (1) a tendency to select on-island and locally available high-quality stone such as fine-grained cherts on Cuba, Hispaniola, and Puerto Rico and Antiguan flint especially the nearby Long Island deposit which was also distributed within the northeast region; (2) most flake extraction via hand-picking of nodules (no mining) occurs at workshops or the lithic sources followed by reduction at occupational sites; (3) an expedient industry focused on production of flakes as tools or useable implements requiring minor or no additional modification; and (4) a shift at certain locations in the production of macroblades to microblades and flakes (Keegan and Hofman 2017: 32; Rodríguez Ramos 2010: 56–57, 60).

Large unretouched blades (Fig. 5a) using freehand reduction techniques mark the macroblade tradition from which side-scrapers, end-scrapers, knife-scrapers, burins, leaf-shaped points, bifaces, and retouched flakes and blades, among other implements, were made. Analogies to other stone-working traditions and use-wear analyses suggest their employment for woodworking and the manufacture of items from perishable materials (e.g., baskets, nets, clothing). Other reduction methods involve the bipolar technique noted for Puerto Rico, the Lesser Antilles, and the Banwari Trace site on Trinidad. At this site small chert nodules were struck between a hammerstone and anvil yielding small, irregular, sharp-edged flakes useful for cutting and scraping purposes

Caribbean Prehistoric Archaeology, Fig. 5 (**a**) Lithic/Archaic Casimiroid microblade examples from sites (left to right): Barrera Mordan, Dominican Republic; Long Island, Antigua; Cueva Tembladera, Puerto Rico (Courtesy of Reniel Rodríguez Ramos). (**b**) Ground stone pestle and grooved axe, Trinidad. (Courtesy of Peter G. Roe)

(Keegan and Hofman 2017: 32; Rodríguez Ramos 2010: 58–62; Wilson 2007: 41).

Ground or use-ground tools comprise large and small pestles, mortars, conical manos, grooved axes (Fig. 5b), hammerstones, pebble tools used as percussors and grinders, notched cobbles or netweights, milling stones, bifacially worked celts, basalt axes, and a widespread Antillean as well as northern South America edge-ground tool modified by grinding or pounding on only the edges. Cuba has a particularly well-developed shell tool industry yielding gouges/hoes, plates, cups, and hammers. Conch shell adzes are also known from the northeast Antilles, while coral files, sharpened bone tips, fishhooks, and needles can be added to the list. The recovered implements reflect a range of inferred activities related to hunting, fishing, collecting, woodworking, canoe building, manufacture of other items, and processing of wild and even cultivated plants. The latter activity indicated, for instance, by the basalt axes that lack a sharp edge making them more useful for soil working/planting than other functions and the presence of wild and domesticated plant remains found on stone tools (see "Subsistence" section) (see Table 3; Keegan and Hofman 2017: 40–42, 48; Rodríguez Ramos 2010: 62–64, 69–72; Wilson 2007: 40–42).

Ground stone disks, bowls, and cups from Cuba, as well as shell and stone beads, disks, and a variety of pendants, are among the more personal wider distribution made artifacts. *Bobitos* or pendants with peripheral grinding to emphasize geometric decorative patterns, and more rarely manatee-bone pendants, and a mother-of-pearl serrated edged pendant have been documented for Puerto Rico (see Table 3; Keegan and Hofman 2017: 40–41; Rodríguez Ramos 2010: 64–68).

Settlements

Settlement system data for this period are limited. Most are open-air sites situated in coastal zones; caves for habitation, in addition to burial and inland riverine and mountain zone locations, are also recorded. The lithic workshops, shell middens, small-sized main occupations, temporary base camps, and special extraction sites are consistent with mobile groups exploiting seasonally available plant and animal resources in addition to permanently accessible raw material sources. There are also indications of the development of a sense of place and of social memory. Several sites display recurrent use and abandonment cycles over centuries such as Krum Bay in the Virgin Islands, Plum Piece on Saba, and Etang Rouge on St. Martin. The Canímar Abajo rock shelter area communities (Cuba) used the same location for two burial phases of roughly 600 years each: 1380–800 BC and AD 360–950. Multiple shell middens in a concentric pattern linked to recurrent if not extended visits are known from Angostura on Puerto Rico and Cayo Redondo on Cuba. Finally, an insular as opposed

to a continental scale of population-to-resource distance ratios, lack of migratory animals, plus areas with adjacent diversified and protein-rich exploitive zones may have provided opportunities for increased residential stability (see Table 3; Keegan and Hofman 2017: 28–29, 42–43, 199 Fig. 7.2, 206, 208; Smith et al. 2018; Rodríguez Ramos 2010: 75–79).

Subsistence

The emerging picture of Lithic/Archaic subsistence is one of flexible, resource-dependent strategies involving a wide range of plants and animals obtained through hunting, fishing, collecting, and for certain groups low-level cultivation. At entry a giant flightless owl, tortoises, the sloth, iguanas, the manatee, marine turtles, and a variety of rodents were present. While recovered faunal remains are minimal, the early blade tools indicate their hunting contributed to high rates of decline or extinction, as with the sloth. The reduction of especially larger land animals through time is compensated for by increased marine proteins from mollusks (conch, oyster, mussels, clams), fishes, and turtles. Coral reefs and seagrass beds appear to be the favored exploitation habitats based on stable carbon and nitrogen isotope ratios from Archaic skeletons. Resource variability or dependency is also observed among sites (see Table 3), reflecting a particular area's most abundant or easiest obtained species. For instance, at Maruca, Puerto Rico, the primary emphasis was on coral reefs, followed by minimal shallow inshore waters and terrestrial locales. At Krum Bay, US Virgin Islands, the emphasis was more evenly divided between terrestrial and shallow inshore waters followed somewhat less so but again equally by freshwater/shore and coral reefs (Keegan and Hofman 2017: 29–30, 33–34, 39–40, 42–43; Wilson 2007: 55).

Evidence for plant management comes directly from botanical remains identified through starch grain and stable isotope analyses and indirectly from the inferred use of soil working and plant processing tools (see foregoing "Material Culture" section), as well as fire or charcoal particulate spikes seen in several core samples from the region. Mexico, lower Central America, and northern South America beginning around 7500 BC onward are home to initial domestication and active exchange of several important subsistence crops including maize, chili peppers, squash, beans, and manioc that to judge by the recovered plant species in Table 4 also included the Caribbean. Mention was made under the "Early Occupation" section of the early 2500 BC plant suite (maize, sweet potato)-tool kit (edge-ground cobbles, milling stones) association in the northeast Antilles, while starch grains identified on grinding stones from St. John on Trinidad now yield the earliest dates in the region for maize, sweet potato, zamia, canna, and chili pepper, at 6000 BC (7790–7670 cal. BP) (see Table 3). Circulation of plants and associated cultivation and culinary knowledge among diverse groups on the mainland was likely via dispersal or exchange while within the Caribbean via maritime population movements and trade.

In addition to the taxa already mentioned, Lithic/Archaic period remains involve a number of fruit-bearing trees, root crops, edible seeds/grains, and other use plants. The spiny palm, West Indian cherry, mastic bully, wild avocado, and yellow sapote are among the edible fruit resources; wild yam, manioc, arrowroot, and yautía can be added to the root crop listing; the common bean and panicoid grass seeds are additional foods, while cossie balsam and wild lime, as well as certain root crops, were used for medicinal purposes. Many were introduced from surrounding mainland zones, but reliance was also placed on native plants once in the region, in particular zamia, a stocky, fernlike plant.

Mindful that presence does not necessarily indicate relative importance, it nonetheless appears that a variety of fruits – spiny palm, West Indian cherry, mastic bully, and yellow sapote – and wild to cultivated root/seed-bearing plants, canna, wild yam, sweet potato, manioc, arrowroot, trianthems (flowering plants), yautía, zamia, haba, the common bean, panicoid grasses, and maize, formed a critical part of the subsistence base throughout the precontact period. Mindful again that the current lack of remains may be due to factors other than actual absence, it also

appears that temporal changes in taxa dependence and relative ranking occurred. For example, under the edible fruits category, sapodilla and wild avocado drop out at the end of Lithic/Archaic, while several new species are only added during the Late Ceramic including quenepa and hog plum. In Puerto Rico and the Dominican Republic, starch grain analysis indicated that zamia and maize changed highest ranking positions through time.

An integrated combination of plant management or procurement systems is suggested: tended fruit-bearing trees along with certain roots like sweet potato and arrowroot in partially forested plots or home gardens; deforested prepared agricultural fields for such plants as manioc, beans, and maize; and gathering or collecting of wild plants like zamia and yam. Deforestation was apparently accomplished via the slash-and-burn method judging from charcoal particulate spikes noted in core samples. This practice involves cutting trees and brush in an area, allowing the vegetation to dry then burning it just before planting to release the bound-up nutrients. Finally, support for the cultivation contribution of the four-source subsistence base should perhaps not be overstated. At the late Lithic/Archaic site of Canímar Abajo (AD 360–950), Cuba, several of the just listed plant species were identified using starch grain and stable isotope analyses (see Table 3). Yet three similarly dated nearby sites did not rely on cultivated plants (Keegan and Hofman 2017: 42–43; Pagán Jiménez 2011, 2013; Newsom 2008: 173, 179–185; Reid et al. 2018: 210–218; Smith et al. 2018).

Pottery

Pottery, like plant management practices, is no longer confined to the succeeding Ceramic Age. A number of sites from the region, in particular Cuba, the Dominican Republic, and Puerto Rico beginning around 2200 BC, have yielded small quantities of ceramics in association with Lithic/Archaic Age assemblages. Characteristics of this Pre-Arawak Pottery Horizon involve small- to medium-sized globular bowls and boat-shaped or navicular forms as the primary vessel types produced by coiling; sand, crushed rock, and quartz grit as the principal tempering agents; open-air firing techniques at low temperatures; and mostly undecorated sherds; decorated examples display painted (red, pink, white, black) and lineal/perpendicular/angular incised, punctate, and modeled designs. The manufacture and decoration variability stand in contrast to the formal structure of Early Ceramic Saladoid pottery outlined below. It is unclear if the adaption was due to surrounding mainland introduction that had an earlier established ceramic tradition or to independent invention. Regardless of origin, the Lithic/Archaic pottery conventions likely influenced and were influenced by succeeding Ceramic Age traditions (Atiles and López 2005; Keegan and Hofman 2017: 43–47; Rodríguez Ramos et al. 2008; Ulloa Hung 2005).

Ideology

Hints of the spiritual and ceremonial life of Lithic/Archaic communities come from worked items and rock art. Of particular note is the finding of three so-called three-pointed objects – two from

Puerto Ferro on Vieques and one from the River Site on Barbuda. The numerous succeeding Early Ceramic period examples are frequently made from the tips of conch shells, as is the case with these examples whose natural triangular shape emphasizes a large central point and encircling base; later versions also exhibit two opposing smaller base points (see Fig. 8). They have been interpreted as representing spiritual forces or *cemís*, based on ethnohistorical sources, an interpretation apparently representing considerable time depth (Keegan and Hofman 2017: 40–42; Rodríguez Ramos 2010: 68–69; Rodríguez Ramos 2013: 135–136).

Rock art also transitions the Lithic/Archaic to Ceramic Age periods with images from the near continental islands of Aruba, Bonaire, and Curaçao, a number of sites on Cuba, and one from the Dominican Republic; no images from Puerto Rico or the Lesser Antilles are currently known for this period. Pictographs largely of abstract and geometric designs predominate in Lithic/Archaic groupings, in contrast to Ceramic period assemblages of more equal numbers of petroglyphs and pictographs with an anthropomorphic focus. The correspondence in artistic representation and distribution pattern suggest another link to the Isthmo-Colombian region (Rodríguez Ramos 2010: 68–69; Roe 2009: 214–218).

Networks

The establishment of extensive inter- and intra-regional trading, exchange, and social networks that mark the Ceramic Age begins in this initial period. In addition to the insular-continental exchanges of subsistence plants discussed above, their inter-island dispersal is also indicated. For instance, the native zamia found at Plum Piece, Saba, was probably imported from Puerto Rico or Hispaniola. Similar networks are evident for raw materials where obsidian with the most likely sources at this time being Colombia and Mesoamerica has been recovered from Maruca, Puerto Rico. Flints, cherts, and volcanic materials were transported from sources to other on- and off-island locations particularly involving freehand flakes and pre-worked cores. Cherts from Puerto Rico are found on Vieques and Krum Bay over a distance of some 260 km, while Antiguan flint especially from the Long Island deposit can be found on Puerto Rico across the Anegada passage (no intervisibility) and distributed within the Antigua-Anguilla area. In sum, both long- and short-distance maritime networks were initiated and maintained within the region and between at least Central and South American areas involving the circulation of people, food stuffs, raw materials, information, and ideological components (see Table 3; Boomert 2013: 142–143; Keegan and Hofman 2017: 205; Rodríguez Ramos 2013: 158, 2013: 134–136).

As noted at the beginning of this section, the old picture of Lithic/Archaic societies is outdated, and a new one has yet to come into focus. Any new regional framework needs to articulate the observed cultural variance with influencing factors that resulted in the multifaceted human-environmental dynamic within interconnected insular and mainland zones. These societies may be described as forgers of a newfound island identity: one involving independent groups though linked through kinship, marriage, exchanges, friendship, and competition and sharing common enough ideologies, technologies, economies, settlement arrangements, and subsistence strategies (see also Keegan and Hofman 2017: 48–50, Rodríguez Ramos 2010: 79–83 for characterizations).

Early Ceramic 800 BC–AD 600

Origins

Questions of when, where, why, and how also dominate the next major in-migration of groups into Puerto Rico, the Virgin Islands, and Lesser Antilles. Like the Lithic/Archaic movement into the region, the Saladoid one should be viewed as a multilayered process involving initial exploration and ultimately permanent occupation phases. Unlike the Lithic/Archaic migrants Saladoid communities bring with them a well-established way of doing things which can be traced back to northern South American societies. Whether of northcentral Amazonian or Andean (Peru,

Ecuador, Columbia) origin, around 1000 BC to early AD, a number of Arawak-speaking populations rapidly expand across the northern inland and coastal continental region from the Guianas to the Orinoco River/delta system and into lower Central America.

Although diverse, these groups shared a common cultural character including interaction (marriage, coercion, and warfare) with Archaic communities, settled village life, intensive subsistence economies, ranking based on heredity and birth order, participation in regional exchange networks, placement of a high symbolic value on foreign items, and external community relations usually of accommodation and acculturation. All or many of these aspects as outlined below were transferred to and conditioned by the novel insular setting.

Among these diverse and interacting societies were those who manufactured a distinctive white-on-red painted pottery, termed Saladoid, named after the Saladero site on the lower Orinoco. While this ceramic style was shared among groups from the Orinoco River valley and coastal Venezuela and into the Antilles becoming the defining type (Table 2b), it should also be pointed out that Early Ceramic pottery exhibits additional influences from this widespread South and Central American Arawak cultural substrate negating a single-source scenario.

Between 800 and 200 BC, multiple integrated communities in multiple phases gradually colonize the region due, like Lithic/Archaic peoples did, to deciding in favor of island resources and sociopolitical contexts over mainland ones. Prospective migrants likely had at least a general idea of what islands were environmentally and socially suitable for colonization through contacts with resident Lithic/Archaic groups or prior Saladoid colonists. The earliest settled islands are in the north – Puerto Rico (Punta Candelario, Maisabel), Vieques (Sorcé/La Hueca), St. Martin (Hope Estate), Montserrat (Trants), Guadeloupe (Morel), Antigua (Indian Creek), and Martinique (Fond Brulé, Vivé) – excepting Trinidad (Cedros, Palo Seco) and possibly the Pearls site on Grenada. Settlement of the Virgin Islands and the southern Lesser Antilles likely from other island locations is later, although their prior exploration or casual exploitation is certainly possible. Direct occupation from northeast Venezuela is again likely for Trinidad and Tobago and perhaps further up the island chain. A pattern of early-north-then-later-south settlement, as was the case for Lithic/Archaic groups, is most consistent with direct voyages from northern South American coastal areas rather than as the island physical layout might suggest a stepping-stone or island-by-island south to north progression. Computer simulations indicate that it would have been faster and less risky via a direct route than island succession (for origin discussion Boomert 2013: 143–144; Callaghan 2013: 283–285, 290; Curet 2005: 27–61, 64–66; Fitzpatrick 2013; Keegan and Hofman 2017: 51–62, 136; Wilson 2007: 59–67, 70–72).

Classification

A migration model involving societies of diverse origins and time periods yet participating in a widely shared cultural ethos provides a context for the debate over the classification of their equally diverse material cultures. Rouse (1992) placed all of the Early Ceramic assemblages in one of three subseries of the Saladoid series – the Cedrosan with the other two (Ronquinan and Sombran) limited to the South American mainland. A fourth division at the subseries or even a new series level may be warranted (see Table 2b; Figs. 2 and 3). Among the shared Cedrosan Saladoid cultural traits is the manufacture of white-on-red or WOR painted pottery. A high percentage of painted and incised motifs occur in Cedrosan assemblages that normally contain a minor percentage of a particular type of decorative feature called ZIC or zoned incised crosshatched. Here incision is used to outline areas that are filled in with finer and lighter incised crosshatching.

Additionally, there are assemblages, termed Huecan after the type site of La Hueca on Vieques, that are instead characterized by unpainted pottery and the use of plastic decorative techniques notably ZIC ware and zoned punctation. Further cultural traits also distinguish the two groups including lithics, where, for example, plano-convex adzes (flat ventral and convex dorsal straight tending

sides diverging toward tapered ends) are lacking in Huecan contexts but present in Cedrosan deposits, a notable distinction since they are considered diagnostic indicators of Cedrosan occupations on Puerto Rico and Vieques.

Huecan and Cedrosan components are found in separate strata as at Hope Estate, St. Martin, and in companion settlements as at La Hueca (Huecan)/Sorcé (Cedrosan) and mixed in the same layer as at Morel, Guadeloupe, with considerable chronological and spatial overlap (apparently excepting Trinidad and the Venezuelan east coast). Inter-group relationships seem to be largely accommodating ranging from minimal to close interaction. The cultural trait and contextual differences have traditionally been related to specific migration trajectories: two separate but common movements from the South American northeast tropical lowlands or a single one from the same area with subsequent differentiation once in the region. At the series level, they would be considered the Saladoid and Huecoid traditions and at the subseries level Cedrosan and Huecan complexes within the Saladoid. At the series level, they would also correlate with the Agroalfarero scheme outlined in Fig. 4: Huecoid Agroalfareros I and Saladoid Agroalfareros II (Boomert 2013: 144; Chanlatte Baik 2013; Curet 2005: 63–65; Keegan and Hofman 2017: 67–71; Rodriguez Ramos 2010: 88–134, 145–146; Wilson 2007: 72–81).

The other major inter-group status in the region concerns the in-migrating Early Ceramic communities and resident Lithic/Archaic populations. Only the latter continued to occupy Cuba and Hispaniola throughout this time period (see Table 2b) along with coinciding settlements in the remaining Antilles, and again it seems excepting Trinidad and Tobago. Prior considerations held that the Lithic/Archaic groups were marginalized, eradicated, or absorbed into the newcomer societies, with little contribution to succeeding Caribbean culture formation, a view that is being challenged as discussed in the following "Late Ceramic" section. Relations are now viewed as likely more amicable. While strains and competition were probable, sustained violent confrontations are not indicated (for instance, lack of defensive structures and site locations). Instead exchanges of food items, processing methods, and stone tool technologies are implied, as well as inter-island trade where, for instance, amber and chert from Hispaniola have been found in Early Ceramic contexts at Punta Candelero, Puerto Rico (Boomert 2013: 143; Curet 2005: 70–72; Rodríguez Ramos 2010: 131–132, 149–155; Wilson 2007: 81–82).

Material Culture

The material culture of Early Ceramic communities displays varied technologies for the production of ceramic, lapidary, woven, wood, shell, bone, coral, and stone items for subsistence, personal adornment, and spiritual purposes. The artifacts were made from local and exotic materials and for home use, as well as inter-island/intercontinental exchange networks. Most households likely produced the majority of needed or desired items. However, the degree of skill as in canoe construction and the high variability in aesthetic expression as in ceramic painted and plastic designs point to a certain level of craft specialization (Keegan and Hofman 2017: 74).

Lithic production in the Early Ceramic both maintains and departs from Lithic/Archaic protocols. Flake tool production is again expedient where flakes and cores display a marked degree of morphological variation with two main reduction procedures. Freehand techniques are employed to yield generalized flakes with useable edges alongside bipolar reduction for microflakes. In the Ceramic context, it has been argued that microflakes and chips were placed in wooden boards to grate cultigens as one step in the food processing chain or for similar uses as the freehand produced ones.

Ground stone implements also tended to be unstandardized as observed in the variety of celts and adzes. Common types in the Puerto Rico/Virgin Islands area include the biconvex or petaloid celt (teardrop shape in plain view where the blade is designed with symmetrical convex surfaces) and the aforementioned plano-convex adze. Their implied use is for woodworking. Edge-ground cobbles, grinding slabs, pestles, and hammerstones, similar to Lithic/Archaic types, are also found in the tool kit (Bérard 2013:

Caribbean Prehistoric Archaeology, Fig. 6 (**a**, **b**) Early Ceramic microlapidary ground stone pendants. (**a**) Vulture with human head in claws (Fewkes 1907: Plate LVI). (**b**) Stone frog shape. (Courtesy of Yvonne Narganes Storde/Centro de Investigaciones Arqueológicas, Universidad de Puerto Rico, Río Piedras)

187–188; Pagán Jiménez 2011: 100; Rodríguez Ramos 2010: 105–106, 114, 124, 130).

A significant departure involves the establishment of a sophisticated microlapidary industry involving the production of small, finely detailed polished beads, pendants, and amulets (Fig. 6a, b). Antillean sourced materials such as serpentine, amethyst, carnelian, quartz crystal, as well as continental jade (Antillean jade seemingly not in circulation at this time) and turquoise were utilized with specialized production centers indicated including La Hueca/Sorcé (Vieques), Morel (Guadeloupe), Pearls (Grenada), and Tobago. Iconographic or pictorial themes involve pendants of beak birds with trophy or human heads (Andean condor or king vulture), frog shapes, and those representing bats and reptiles (Boomert 2013: 148; Chanlatte Baik 2013: 179; Keegan and Hofman 2017: 64, 76, 211; Rodríguez Ramos 2010: 101–102, 2013: 159–160).

Varied purpose artifacts were made from additional materials. Conch shell axes and adzes; stingray-spine projectile points and shell atlatl spurs pointing to use of spears and arrows; bone needles for perhaps making clothing or fishing nets; shell and bone fishhooks, beads (discoidal, cylindrical, biconvex, olive shapes), and amulets; gourd containers and woven baskets; clamshell scrapers plus shell hammers, picks, and gouges/hoes; wooden canoe paddles, seats, and amulets (two from Morel, Guadeloupe, representing a dog and a jaguar); coral abraders and drills; conch shell and mother of pearl beads; and a jaguar tooth pendant from La Hueca (Vieques) that isotopic analysis indicates came from a northwest Venezuelan animal (Bérard 2013: 188; Keegan and Hofman 2017: 67, 70, 76).

Another significant departure from Lithic/Archaic Age material culture is the widespread production and use of ceramics. The superior quality and aesthetic appeal characterize a strongly shared or homogeneous tradition that stylistically draws from a common set of decorative modes, design arrangements, and shapes to create particular expressions. Cedrosan ceramics are thin, well-fired, and made via coiled clay strips

(Fig. 7a, b). Vessels tend to be straight sided and sharply angled whose forms include inverted bell outlines, jars, dishes, incense burners (decorated/undecorated cylindrical, bottomless forms with nearly closed tops), and open bowls in hemispherical, boat or kidney, and turtle shapes. Decorative modes involve a red-colored slip applied to all or part of a vessel and white-on-red (WOR), black-and-red, and polychrome (red, white, orange, black) often stylized geometric painted motifs, in addition to straight/curvilinear incised and zonal outlined designs. D-shaped, rounded, and perforated lugs or handles are present, as are rim projections like flanges and points.

Caribbean Prehistoric Archaeology, Fig. 7 (**a**–**e**) Early Ceramics. (**a**) Saladoid white-on-Red decorated external rim sherd. (**b**) Saladoid red, white and orange polychrome sherd. (**c**) Huecoid rim sherd with incisions, knob and rounded points. (**a**–**c**) (Courtesy of Yvonne Narganes Storde/Centro de Investigaciones Arqueológicas, Universidad de Puerto Rico, Río Piedras). (**d**) Saladoid white-on-red open bowl with modeled legs and zoomorphic face. (**e**) Saladoid modeled bird *adornos*. (**d**, **e** Courtesy of Peter G. Roe)

The lack of WOR and polychrome painting focusing instead on plastic decorative features including geometrical zoned incised lines and incised parallel punctations sometimes filled with white or red/pink paint defines Huecan pottery (Fig. 7c). Other incised designs comprise crisscrossing rectangular, triangular, and spiral elements over the entire vessel. Typical shapes again made from coiled clay strips comprise hemispherical bowls, jugs, bowls with and without pedestals, double-spouted globular vessels, and effigy bowls with zoomorphic modeled motifs (Fig. 7d). Common to both traditions are griddles or large round flat disks smooth on one side and usually rough on the other used for processing and cooking plant foods and breads and modeled zoomorphic and anthropomorphic forms or adornos on handles and rims in addition to the just noted effigy bowls (Fig. 7e). A range of stylized to naturalistic presentations are evident involving an equally impressive array of animals – armadillos, dogs, monkeys, manatees, bats, vultures, owls, pelicans, ducks, parrots, snakes, crocodiles, frogs, and turtles – referencing both a continental homeland and new insular environment with implied symbolic content (for ceramics see Chanlatte Baik 2013: 178, 181–182; Pagán Jiménez 2013: 399–401; Keegan and Hofman 2017: 64, 66–67, 69–70; Rodríguez Ramos 2010: 94–95; Rouse 1992; Waldron 2016; Wilson 2007: 67–70).

While there is great uniformity within the Early Ceramic tradition, variability is indicated by the number of styles presented in Table 2b. The ceramic assemblages have been grouped in the Rouse (1992) scheme into a twofold sequence of early 500/400 BC–AD 300/400 and late AD 300/400–600/800 phases, with the later phase lasting longer in the Lesser Antilles. Early to late phase distinctions in the Lesser Antilles include an increase in WOR design complexity, with polychrome painting, rim flanges, and incense burners not appearing until the end. In contrast the Hacienda Grande to Cuevas transition in Puerto Rico involves among other traits the eventual elimination of polychrome painting and a decrease in vessel forms (Peterson et al. 2004: 24–26).

Another factor in the region's ceramic development concerns the formal contact between Barrancoid communities of the lower Orinoco and Saladoid ones of Trinidad and Tobago. While the Barrancoid series has its mainland origins around 1500 BC from the Ronquinan Saladoid subseries, its influence on Cedrosan pottery is dated to AD 300–500. The interaction of the potters of the two series is particularly notable on Trinidad and Tobago suggesting these islands as transit points for, and on-island production of Barrancoid traits such as zoned painting, a particular form of *adorno* (modeled-incised hollow-backed), and rims frequently polished with a pinkish-buff color. The spread of these influencing traits was uneven, strong in the Windwards and less so in the Leewards, and it seems not at all for Puerto Rico and the Virgin Islands (Boomert 2013: 146–147; Peterson et al. 2004: 25; Rouse 1992: 75, 84–85; Wilson 2007: 65–67).

Settlement

While Early Ceramic settlement types include camps, farmsteads, procurement and workshop locations, and rock art sites, it is the large villages that distinguish the system. Large villages typify the Early Ceramic settlement system that also includes camps, farmsteads, and procurement and workshop locations, in addition to rock art sites. The norm was for continuous occupation over centuries with a tendency to be located in coastal over inland (on small islands a few kilometers from the sea) zones. On Puerto Rico, for instance, many of the earliest sites are coastal followed by expansion inward along river valleys. Hierarchical ordering is not apparent until the end of the period. The internal configuration presently documented commonly consists of large houses and from one to a few midden mounds (dense concentrations of high-quality artifacts like ceramics and lithics, food remains, and at times burials) arranged in a circular, oval, or horseshoe shape around an open, central plaza that frequently also contained burials. The central plaza is the assumed focal point for community-wide secular, ceremonial, and mortuary activities.

Golden Rock on St. Eustatius in particular exemplifies internal village structure. The site is

dated to AD 200–800/900 after the end of the Saladoid on other islands although the ceramics are clearly Cedrosan. Excavations of part of the site reveal a series of large and small structures fronting an open plaza with burials between 6 and 19 m in diameter. Six of the large circular or oval structures were interpreted as houses, some with windbreaks, with the remaining smaller post hole outlines identified as household support features including a men's hut. Eleven burials were excavated: one was a child with 81 quartz beads. The deep post mold foundations of the houses and associated possible windbreaks have been interpreted as evidence for hurricane protection measures and as analogs to South American lowland Amazonian large, tall conical shaped communal *maloca* houses. The Golden Rock large examples might have accommodated as many as 60 individuals (Bérard 2013: 191; Ensor 2013: 87–88; Keegan and Hofman 2017: 71–73, 93–95; Samson 2013: 367; Wilson 2007: 88–91).

Subsistence

Early Ceramic peoples engaged in hunting land animals, fishing, and mollusk collection but also engaged in full-scale, broad-spectrum cultivation. As outlined in Table 4, they also appear to have relied upon a mix of plants brought with them or obtained through continued mainland ties or local Lithic/Archaic group exchanges, in addition to native species. Root/seed crops are prominent and include all of those utilized by Lithic/Archaic peoples – canna, yam, sweet potatoes, manioc, arrowroot, yautia, zamia, haba, the common bean, panicoid grasses, and maize – plus new additions. Added fruits include the star apple and guaba, while the medicinal plant list is expanded.

The once-considered primary reliance on manioc during this and the Late Ceramic period, widely noted in the literature, has been amended. Recovered botanical remains including seed, wood, and starches from microflakes-as-graterboard teeth, ground stone tools, and the clay griddles or *burénes* involved in the production and processing of plant foods noted above instead suggest a more equitable and changing-preference/resource available reliance on the entire range of identified taxa. Cultivation practices mirror those outlined for Lithic/Archaic communities: maintenance of multipurpose home gardens, slash-and-burn procedures for larger cleared plots, and collection of wild plant resources. Intensification efforts at the end of this period are seen in the hillside terraces at Las Planás, Puerto Rico, designed for soil retention/water filtration (Keegan and Hofman 2017: 73, 135, 210; Pagán Jiménez 2011, 2013; Newsom 2008: 173, 179–185; Ortiz Aguilú et al. 1991; Reid et al. 2018: 212, 214, 216–218).

Exploited terrestrial animal resources comprise a number of small rodents like the hutias, birds, and reptiles such as iguanas, crocodiles, and turtles, in addition to land crabs and snails. Imported animals from South America include the agouti, armadillo, opossum, guinea pig, and dog. Their roles and significance within the social and economic systems were apparently variable. The guinea pig and dog were domesticated, while hutias, Muscovy ducks, and turtles may have been managed. Their consumption is certainly indicated, although the relatively low numbers of such remains in archaeological contexts suggest a minor contribution to the overall diet. Dog burials, normally alongside human interments, point to their use in hunting inferred from teeth modifications for possible mouth restraining devices and as pets; the later function may also be ascribed to other animals including the capuchin monkey and macaw bird.

Aquatic protein sources apparently accounted for a larger and increasing proportion of the diet. Stable isotope analysis indicates that initially terrestrial protein sources like the hutia, iguana, land crabs, and freshwater fish were targeted, shifting over time to marine taxa involving a diversity of fishes like parrotfish, groupers and snappers, sea turtles, mollusks in particular queen conch, and less importantly marine mammals. Studied skeletal remains point to generally healthy populations, but with a number of dental issues involving caries and extreme wear; the latter might reflect a starch and gritty diet. Wear along incisor interiors noted only in females could relate to this gender's role in processing vegetable fibers (Keegan and Hofman 2017: 73–74; Reid et al. 2018: 215–216).

Sociopolitical Structure

Ethnographic and ethnohistoric information form a basis for consideration of Early Ceramic sociopolitical structure. The widely spaced and largely non-differential nature of the villages suggests they were mainly autonomous, although the artifact commonalities and reconstructed extensive networks certainly indicate strong inter-village connections including marriage, kinship, social, and competitive ties.

These societies have long been considered tribal and unranked. An egalitarian nature is inferred via reference to South American lowland groups where leadership is ascribed but not inherited. Burial data tends to support this view as differential status indicators at death are minimal. The few grave goods can be considered primarily personal items comprising ceramics and foodstuffs, although the 81 beads of the child burial at Golden Rock noted under the settlement section suggests an unearned notable status.

While inter-village relationships were likely more or less equal or heterarchical, hierarchical intra-village relationships need not be discounted. Local community leaders, also referred to as "big men" in the literature, might have been able to exert influence over internal and external matters from labor organization to trading networks to raiding/warfare based on personal qualities that would have attracted adherents. Large villages would be consistent with lineages or other sub-village social segments having more prestige than others. The range in vessel forms, craftsmanship, and variety of designs suggest their use in ceremonial contexts (marriages, marking trading alliances) involving public displays of food and other items that might have expressed status differences or kinship ties (Boomert 2013: 146; Chanlatte Baik 2013: 180; Keegan and Hofman 2013: 76–79, 93–95, 212–214).

Ideology

The ideological system hinted at in the Lithic/Archaic Age becomes more fully envisioned for the Early Ceramic. Ethnologies of present South American lowland tribes and ethnohistoric accounts of Amerindians at contact indicate strong continuities in world view and religious principles of the two descendent mainland and Antillean cultures. Common core aspects likely introduced in the preceding age form a firm foundation in the Early Ceramic for succeeding developments in the Late Ceramic.

Reconstructed ideological aspects are outlined in Table 5 and are underlain with a belief in a three-tiered cosmos and a deep-seeded animistic world view. The cosmos consisted of an upper Sky World associated with benevolent spirits, a middle plain or human Earth World, and a watery Underworld also home to the dead all connected via an *axis mundi*. Vital forces or numinous powers enlivened humans, animals, the deceased, and a range of natural forces and objects including trees, smells, rivers, and hurricanes. These spiritual forces were codified or identified as *cemís* that were likely undifferentiated (informal identification of deities and associated relationships and powers) in the Early Ceramic. They could make themselves known, normally requiring a shaman to perceive their presence and if deemed necessary undertake their physical transformation into a range of objects such as wood, stone, perishable materials, and even rock art. *Cemís* were also associated with specific beneficial or harmful powers to humans like causing illness, producing rain, and favoring cultivation. Also associated with this cognitive outlook were notions of hidden and present realities, human/animal/spirit transformations, and drug-induced visions (see in particular Boomert 2000: 445–490; Hayward et al. 2014: 207–208; Oliver 2005, 2009; Roe et al. 2018: 180–183; Siegel 1997).

A low-level religious structure is indicated, largely in the hands of shamans charged with curing and healing affairs. In addition they helped ensure the wider community's health and well-being via contact with and supplication of spirits in the other realms along the axis mundi. They were aided in these endeavors by the taking of hallucinogenic drugs. Community to household burial ceremonies, rituals, and practices were likely important integrative mechanisms. The numerous inter-village economic, social, and political relations were also likely carried out within a ceremonial context.

Caribbean Prehistoric Archaeology, Table 5 Reconstructed ideological components of early and late ceramic precontact Caribbean culture

Category	Early Ceramic	Late Ceramic
Cognitive features		
	Belief in a three-tiered cosmos	Belief in a three-tiered cosmos
	A deep-seeded animistic world view	A deep-seeded animistic world view
	Codification of spiritual forces as cemís, largely undifferentiated or unranked	Development of systematic relationships among named cemís; definition and ranking of cemís as deities or departmental gods
	Beliefs involving hidden and present realities, human/animal/ spirit transformations, drug-induced visions	Beliefs involving hidden and present realities, human/animal/spirit transformations, drug-induced visions
	Strong common symbolic system	Diverse symbolic system
	Rich mythological tradition	Rich mythological tradition
Practices		
Rituals ceremonies	Private household, public village, limited inter-village public	Private household; private societal segments; public village, open inter-village, and inter-regional
Structural features		
Organization	Decentralized	Increasing centralization
Practitioners	Laypeople, shamans	Laypeople, shamans, chiefly elites
Belief system	Unenforced; varied interpretations	Increasing formal understandings
Material correlates		
Structures	Marked and unmarked landscape features, burial locations, village centers without enclosures	Marked and unmarked landscape features, burial locations, village centers with and without enclosures
Objects	Different scaled everyday items including ceramics (designs, shapes), microlapidary pendants/amulets, three-pointers, rock art	Certain ceramic designs; elaboration in size and design of three-pointers; introduction of ground stone religious/political objects (stone collars, elbow stones); increase in numbers, location, and image complexity of rock art
Substances	Particular foods, hallucinogenic ingredients	Particular foods, hallucinogenic ingredients

Material correlates of certain of these cosmological and religious beliefs and practices have been inferred. In common with present South American village layouts, the Early Ceramic roughly circular and concentric settlements are considered to replicate the three-level cosmic order. Horizontally the earthly level's village's central space is considered sacred, the household and mounded midden areas as every day or secular, and the surrounding forests and fields as the natural world of plants and animals. Vertically the earthly plain is bounded by the upper sky and lower underworlds with the axis mundi physically and symbolically located at the community's center.

The transformed objects containing the manifested cemí spirits were also termed cemís and are linked to three-pointers or the triangular shaped artifacts noted under the ideology discussion of the Lithic/Archaic Age. In the Early Ceramic, the range of materials – stone, bone, shell, and coral – increases, as does their numbers and distribution (Fig. 8). The majority are small (3–7 cm lengths) and undecorated; Later Ceramic examples include much larger ones (15–30 cm), often sculpted with anthropomorphic and zoomorphic motifs.

The belief in an animistic world view and in human-animal or mythic transformations may be seen in the plurality of modeled and incised human and zoomorphic forms. Suggested Shaman-related items include vessels with *adornos* exhibiting pictorial dualism or different human/animal forms depending on the viewing angle. One example has

Caribbean Prehistoric Archaeology, Fig. 8 (**a**–**c**) Large and small stone *cemís*. (**a**) Early Ceramic small (3–7 cm range) undecorated examples with basal incisions. (Courtesy of Peter G. Roe). (**b**) Late Ceramic large worked anthropomorphic design emphasizing a center and two opposing points. (**c**) Late Ceramic large worked anthropomorphic design in single triangular shape (**b**, **c** Fewkes 1907: Plates XXXII and XLVI, respectively)

a front-facing squid-like animal whose features at two other angles form another sea animal and a bulging-eyed fish. Such visual ambiguity might have facilitated contact with the spirit world, as would effigy vessels which could have temporarily held a shaman's guardian spirits during such intercommunications. The use of hallucinogenic substances involving tobacco, pepper, *cohoba*, or a mixture to induce ecstatic-visionary trances is partially documented at this period (see Table 5), but primarily inferred via incense burners, in particular decorated examples with *adornos* for the burning of or enhancement of such ingredients, double-spouted bowls for their inhaling through the nostrils, and small biomorphic dishes for snuffing.

In addition to the standardized images and design motifs found on the ceramics and microlapidary items pointing to a strongly shared symbolic system, modeled *adornos* have been linked to a rich mythology involving origin stories, culture heroes, and mythic personages. Visual imagery reflecting ideological/mythic linkages also involves another medium: the surfaces of relatively stationary rock formations. Petroglyph sites from St. Lucia and St. Vincent in the southern Lesser Antilles may date from the end of the Early Ceramic around AD 200–300. In contrast to the ceramic strongly *adorno* zoomorphic focus, the petroglyphs represent simple humanlike facial and facial/body images along with geometrical (circles, spirals, lines) and abstract (regular/irregular lines, dots) designs (Boomert 2013: 145–146; Hayward et al. 2009b; Hayward et al. 2014: 221, 224; Keegan and Hofman 2017: 79–80; Roe et al. 2018: 184–185; Siegel 1997; Reid et al. 2018: 214–215; Waldron 2016).

Networks

The circulation of material and nonmaterial cultural valuables established in the Lithic/Archaic period only intensifies in the Early Ceramic. Exchange patterns are multi-scalar – individual, artisan groups, sociopolitical segments, and communities – and multi-vector, intraisland, inter-island, and inter-island/continental. These organized trade and production networks operated at a pan-Caribbean level

or within more localized interaction spheres (higher degree of interaction within than without culturally bounded island/continental groups) involving such components as:

- The continued on- and off-island transport of fine-grain cherts and flints for flake tool manufacture; Antigua and St. Martin are particular insular sources.
- Inter-island movement of local and mainland sourced areas of preforms or unmodified cores for celt and adze production.
- Inter-island exchange of ceramic vessels especially between volcanic and limestone islands.
- Inter-island/continental trade centered on high valued items of marked aesthetic quality as in the microlapidary pendants, amulets, and beads; also pieces of *guanín* a gold-copper alloy imported most likely from the Isthmo-Colombian area to Puerto Rico.
- Inter-island/continental exchanges of plants and animals
- Local community leader organization of trading systems
- Circulation of social valuables like songs, myths, knowledge
- Wide range and homogenous nature of the materials suggest a strongly shared cultural aesthetic, symbolic system and ideology (Keegan and Hofman 2017: 75–76; Valcárcel Rojas and Martinón Torres 2013: 509, 510 with Table 34.1; Rodríguez Ramos 2010: 103–104, 2013: 159–166).

Being newcomers to the region, Saladoid and Huecoid communities can also be viewed as forgers of a new insular outlook. An identity that transitions from early colonization efforts involving the wholesale introduction and reliance on standardized settlement and subsistence strategies with a robust sense of shared cultural values to a more flexible, adaptive, and varied outlook beginning at the end of the fourth century AD. While a high level of continuity between the two phases is maintained, changes include occupation of new on-the-same-island, as well as different island locations, a decline in ceramic variety suggesting a lessening of social norms and an increasing reliance on local island resources at the expense of mainland ones. This developing diversity in cultural expressions related to local conditions or accommodations is magnified in the succeeding Late Ceramic period (Bérard 2013; Keegan and Hofman 2017: 80–83).

Late Ceramic AD 600–1500

Intensification, diversification, expansion, and regionalization mark Late Ceramic cultural dynamics. Intensification is seen in a two-tiered class system, chiefdoms, and increased exploitation of the available resource base. Diversification is reflected in the number of new ceramic types and lithic tradition changes, while population growth and movement into the interiors of already settled islands takes place along with the occupation of new ones that finally includes Jamaica and the Bahamas. These currents were not uniform across the region providing a mosaic of multiple, distinct, and integrated-at-different-scales societies operating within changing cultural and physical environments. The arc of cultural development shifts from initial entry and adjustment phases of two major migratory waves to developed Caribbean cultural identities on the eve of European contact.

Material Culture

Late Ceramic material culture, while demonstrating similarities and differences with previous periods, reflects an emphasis on more loosely structured localized production and a shift from insular and insular/mainland circulation of exotic raw materials and finished personal goods to high-quality/high aesthetic objects tied to social status, ethnicity, or both. Mainland area ties continue, but insular sources and exchanges take precedence.

For the well-studied lithic assemblages of Puerto Rico, continuity, change, and reemergence of traits, in addition to new technological excellence across various media, are evident. For instance, the two major production strategies of bipolar and freehand reduction that were observed in Lithic/Archaic and Early Ceramic contexts are not only present but vary in emphasis from site to site. While biconvex celt production in general is

maintained, that of the plano-convex adze decreases and is absent in assemblages by AD 800 matched by the increased use of petaloid celts (teardrop in outline where the blade is designed with symmetrical convex surfaces). Guatemalan jadeite for some celt production testifies to the continued movement of such celts and contacts with the Isthmo-Colombian area.

The differential reliance across sites on Lithic/Archaic and Early Ceramic lithic traditions is also noted in culinary practices: grating foodstuffs via microflakes-in-grater-boards (Early Ceramic) versus pounded and ground tubers and grains via such tools as edge-ground cobbles and metates or flat smooth-surfaced stones (Lithic/Archaic). Lithic/Archaic items like net sinkers or weights, conical manos, and stone spheres are again observed and the latter at other Greater Antillean non-Puerto Rican sites as well. The intensified use of local materials, the variety in plant processing tools, and co-occurrence of eight distinct lithic traditions derived from prior periods all point to increasing insular exchanges among different resident social and ethnic groups (Keegan and Hofman 2017: 85–86, 92, 103; Rodríguez Ramos 2010: 146, 161–192).

Long-distance regional-mainland contacts, focusing on a different class of materials – high-quality prestige objects – continue, particularly those of ground stone and wood (Fig. 9a–f).

Examples of exotic and sumptuary exchange items include:

- Tiny cherry jewel box clam beads (*Chama sarda*)
- Conch shell beads with notched edges
- Large quartz and diorite beads
- Carved greenstone and other exotic stone pendants
- Shell masks or *guaízas* (small pendants made from conch shell with detailed incised and unique humanlike faces often emphasizing the eyes and mouth; highly valued exchanged items likely in special contexts) (Fig. 9a)
- Shell and stone three-pointers or *cemís* (relatively abundant mid-hundreds; large 15–30-cm-wide undecorated and elaborately incised and sculpted examples that incorporate a prominent central point and opposing basil points; anthropomorphic and zoomorphic designs) (see Fig. 8b, c)
- Stone heads (sculpted anthropomorphic three-dimensional heads) (Fig. 9b)
- Stone collars (pecked and ground large – 45 by 31 cm – oval rings; all with minimal designs and many with elaborate zoomorphic and anthropomorphic images along with geometric motifs) (Fig. 9c)
- Elbow stones (considered a labor-saving shorthand version of stone collars with only part of the stone ring reproduced with remainder replaced by wood, basketry, or cloth; limited in number; most undecorated, rest with anthropomorphic images) (Fig. 9d)
- Monolithic or one-piece axes (Fig. 9e)
- Wooden statues (elaborately carved and up to a meter tall, anthropomorphic and zoomorphic depictions; considered to be cemí representations or as receptacles for preparation of hallucinogenic substances like *cohoba*)
- Wooden and stone seats or *duhos* (low, small, sometimes with a large curved back carved wooden or sculpted ground stone seats; overall design incorporates anthropomorphic and zoomorphic shapes with legs and heads detailed as supports or as integral terminal elements; others with complex incised designs) (Fig. 9f)
- Cold-hammered gold sheets from nuggets (of high value; ethnohistorically, sheets noted as used to adorn *guaízas*, snuff or *cohoba* inhalers, wooden statues, and other objects all with chiefly or religious linkages)
- Imported gold-copper alloy *guanín* (of high value; strong chiefly, religious associations; archaeologically gold and *guanín* recovered mostly as perforated sheets with other examples of a gold nose ring, a human figure, bell, sphere, bead, bird figure; almost all items from Late Ceramic or a native contact period burial)

Their limited numbers and superior aesthetic details likely reflect their high value to those involved in their production, circulation, and use. Distributions within the region vary. Shell masks or *guaízas* are scarce with a wide distribution from Cuba to the Windwards, whereas the

Caribbean Prehistoric Archaeology, Fig. 9 Late Ceramic sumptuary items: (**a**) *guaíza* or shell mask; (**b**) stone head with anthropomorphic face; (**c**) oval stone collar, plan view; (**d**) elbow stone with anthropomorphic face; (**e**) monolithic stone axe and (**f**) wood *duho* with anthropomorphic head and legs for support and incised elongated back. (Fewkes 1907: Plates LXXXVII, LIV, LXVII, LXIX, XIV. XCII, respectively)

more abundant large decorated three-pointers and stone belts are mostly limited to Hispaniola and Puerto Rico. The related elbow stones are concentrated in Puerto Rico. *Dujos* are most common on Hispaniola, Puerto Rico, and the Bahamas with limited examples elsewhere in the northern Caribbean. The gold sheets have sources on Hispaniola and Cuba, while *guanín* is likely a direct maritime import from the lower Central American-Colombia region. Most of the gold/gold alloy pieces are from Cuba followed by the remaining Greater Antilles area. The movement between, and common use *dujos* in, the Caribbean and Central America is suggested; for instance, an ethnohistoric reference by a Nicaraguan chief uses the word *dujo* for his bench (Keegan and

Hofman 2017: 143–144; Hayward et al. 2014: 222–225; Mol 2007; Rodríguez Ramos 2010: 196, 206–208; Valcárcel Rojas and Martinón Torres 2013).

Three dominant trends in Late Ceramic pottery production involve a significant expansion of pottery types, their overlapping and intermixing nature, and an emphasis on plastic rather than painted decorative designs. Seven to nine series are recognized frequently with multiple subseries and styles as listed in Table 2c. Rouse (see also Figs. 2 and 3) organized the ceramics of the Greater Antilles into one series: the Ostionoid with three subseries, the Ostionan, Meillacan, and Chican. Alternatively, the three subseries are classified at the series level: Ostionoid, Meillacoid, and Chicoid. Lesser Antillean pottery is grouped into the Troumassoid, Suazoid, Cayo complex, Arauquinoid, Mayoid, and Dabajuroid series, albeit with Chican Ostionoid/Chicoid ceramics found in the northern Lesser Antilles at the end of the period. With two exceptions, they are considered to represent localized insular developments although with varying degrees of insular and – in the case of Trinidad's Mayoid ceramics, South American – mainland influences. The two exceptions concern the Guayabitan Arauquinoid subseries on Trinidad and the Dabajuroid series of Aruba, Bonaire, and Curaçao that derive from northern South American ceramic traditions.

Two aspects of Rouse's model come into play regarding the distribution and timing of ceramic categories. The first concerns the statement that ceramic traditions tend to be more alike across certain passages than from the same island, a topic introduced under the "Terminology and Chronology" section. Those passages comprise eastern Puerto Rico and the Virgin Islands, western Puerto Rico and Dominican Republic across the Mona channel and Haiti across the windward passage with eastern Cuba (Rouse 1992: 52 Fig. 14). The second involves the empirical observation that the ceramic categories do not necessarily represent discrete units in time and space. For example, Cedrosan Saladoid traits and pottery are found for a few hundred years in Puerto Rico and the Lesser Antilles after the introduction of Late Ceramic types that when radiocarbon date ranges are considered for Puerto Rico exhibit considerable style overlap. Instances of different pottery types at the same or nearby sites are not uncommonly recorded. A similar situation is noted for Dominican Republic ceramics (Keegan and Hofman 2017: 85–87, 125–128, 215–216; Peterson et al. 2004: 27–28; Rodríguez Ramos 2010: 155–161, 192–193, 211–212).

The trend from the later Saladoid and Huecan styles (circa AD 400–600) to initial Late Ceramic styles has often been described in the literature as one of simplification. The highly diverse and well-executed poly- and bichrome painted designs and adorno modeling are replaced by an increasing importance on incised decorative features applied to less well-made vessels among other distinctions (Fig. 10a, b). Painting and slipping are still found among the pottery style description in Table 6, including Troumassan

Caribbean Prehistoric Archaeology, Table 6 Select descriptions of late ceramic pottery categories

Pottery descriptions	Source
Chicoid ceramics (AD 600–800) – thick, soft, and highly polished; wide range of vessel shapes, including effigies and white-slipped bottles. Jars (potizas) are common; paste is gray to brown. Flaring rims, some with punctations outward flaring. No applique. Lugs are large and modeled, and large strap handles are present. Incisions are broad-lined with smooth and rounded edges, shallower, and widely spaced and occur in circular, oval, and rectangular panels. Straight lines typically end in a dot	Keegan and Hofman (2017: 121)
Chican Ostionoid subseries (AD 1200–1400) – incisions on shoulders of incurving bowls, with some red-slipped vessels present; the absence of strap handles; biomorphic modeled-incised head lug adornos among the decorations	Peterson et al. (2004: 29)
Monserrate style (AD 600–900) – hemispherical or boat-shaped vessels with strap handles and tabular lugs; mainly plain (but red-slip or black exterior occur). Not incised	Keegan and Hofman (2017: 88)
Santa Elena style (AD 900–1200) – tends to be thick, coarse, and rough; well-rounded, shoulder-less bowls common, generally flat bases; unpolished surfaces; rim points, ovoid and rectangular lugs/handles, and strap handles present. Decorations are simple and executed in applique or molded. Incised and punctated designs dominant with red painting	Peterson et al. (2004: 27) and Keegan and Hofman (2017: 88)
Capá style (c. AD 1200–1500) – less well-made being heavily impregnated with sand; vessels (which are dominantly hemispherical) crumble easily. They are, however, frequently decorated, with anthropomorphic lugs. Modeled, incised, and punctate motifs predominate. Designs mimic the Boca Chica style, but are less elaborate and less well executed. Strap handles are absent	Keegan and Hofman (2017: 104)
Esperanza style (c. AD 1200–1500) – vessels are predominantly hemispherical with rounded bases, incurving sides, and a blunt, rounded keel. Paste is coarse, with an average thickness of 7 mm. Incised designs restricted to shoulders, with crude lugs/handles of anthropomorphic appearance. Painting and strap handles are absent	Rouse (1952: 352–354) and Keegan and Hofman (2017: 104–106)
Boca Chica style (c. AD 1200–1500) – characterized by thicker and sturdier vessels with fine, hard, smoothed, and occasionally polished surfaces. Vessels include round or boat-shaped with inturned rims and spherical bottles. Presence of incised lines beginning and ending with punctations (line-and-dot); flat and prismatic lugs/handles with anthropomorphic designs	Rouse (1952: 347–350) and Keegan and Hofman (2017: 104)
Pure Ostiones (AD 600–900) – traits carried over from Saladoid pottery include tabular lugs, strap handles, and red-painted and slipped surfaces. Distinctive traits are boat- and kidney-shaped vessels, with incurving bowls (cazuela); biomorphic (bat-head) handles; the presence of pink or lilac slips that entirely covered the vessels; designs in black paint	Peterson et al. (2004: 27)
Modified Ostiones (AD 900–1200) – traits carried over from Saladoid pottery include tabular lugs, strap handles, and red-painted and slipped surfaces. Distinctive traits are boat- and kidney-shaped vessels, with incurving bowls (cazuela); biomorphic (bat-head) handles; incised designs; the presence of pink or lilac slips that entirely covered the vessels; designs in black paint	Peterson et al. (2004: 27)
Mellacoid ceramics (AD 600–800) – vessel shapes include hemispherical bowls and boat shapes, with rounded rims that typically turn inward at the shoulder (*casuela*). Paste color varies from red to gray to black. Decorations are limited to the panel between the shoulder and the rim and include sigmoid and other appliqué, punctations on the body and lip, and adornos that rise above the rim on opposite sides of the vessel. Some lugs are anthropomorphic and are built of appliqué. Strap handles are present. Common incised lines include crosshatching, oblique parallel lines, and straight lines that do not end in dots	Keegan and Hofman (2017: 120–121)

Caribbean Prehistoric Archaeology, Table 6 (continued)

Pottery descriptions	Source
Troumassoid series/Troumassan Troumassoid subseries (AD 500–600) – characterized by vessels that are boat- and kidney-shaped, round bottomless, double and hemispherical, and inverted bell-shaped bowls. Cylindrical pot stands, jars, and effigy bowls were common. Decorations include polychrome painting of white, red and black or red, and black combined with curvilinear incisions; painted scrolls on a buff surface	Peterson et al. (2004: 28)
Mamoran Troumassoid subseries – vessels are thick, with white-on-red painting and straight parallel designs, although curvilinear incision continued. First appearance of scratched pottery. Handles became vestigial	Peterson et al. (2004: 27)
Mamoran Bay style – red-slipped surfaces replaced bicolor and polychrome painting, with simplified patterns, broad-lined incisions, with curvilinear or parallel linear designs. Pottery was less well-finished. Rims were thickened by adding a coil of clay. Incised elements tended to be deeper, narrower, more irregular, and U-shaped	Peterson et al. (2004: 27)
Early Suazoid Troumassoid subseries (AD 1000–1200) – thick, coarse, and soft pottery with scratched or scraped surfaces; inward thickened rims; legged, pedestal, or annular bases; legged griddles; and triangular griddle rims. Decorations include broad-line incisions on red-slipped surface and modeled-incised zoomorphic head lug adornos. Monochrome red-painted surfaces typical. Vessel shapes are simple, unrestricted, or restricted bowls and necked jars	Peterson et al. (2004: 28)
Late Suazoid Troumassoid subseries (AD 1200–1500) – less-finished and crude, with scratched, finger-indented surfaces and legged vessels and griddles. Often undecorated, although some have red paint, linear or zoned painting, or parallel incisions, circles, or scrolls on the rims or walls. Flat human-head adornos with flaring pierced ears, figurines, and clay pestles were typical	Peterson et al. (2004: 28)
Cayo complex/style (c. AD 1250) – incisions on a flat rim, cone-shaped collars and bodies, and typical applique decoration in the form of adornos made of perforated clay balls. Multi-convex vessels with anthropomorphic faces in applique and *caraipe* (tree-bark) temper	Peterson et al. (2004: 28)
Bontour complex (AD 500–700) – shell-tempered pottery with minimal decorations, sparse punctate, and incised or gouged motifs; absence of head lugs	Boomert (2013: 149)
Mayoid (AD 1500–1700) – linked to Native-European contact; characterized by exclusive use of *caraipe* temper and strong similarity between typical Mayoid cooking jars and Arawakan groups in Guianas	Boomert (2013: 151)

Caliviny polychrome of the Lesser Antilles where normally vessels possess overall red paint with additional black-painted curvilinear (scroll) and linear (geometric and parallel designs) motifs. More common however are plain-tending ceramics like those of the Monserrate style – here an unpainted open bowl with strap handles (Fig. 10a) – and incised motifs like those of the Santa Elena style, here thick straight-dot-ending and curved lines, as well as open punctates on plain handles (Fig. 10b; both styles from Puerto Rico).

Subsistence

Major components of the subsistence base laid out under the Lithic/Archaic and Early Ceramic periods – hunting of land animals, fishing and mollusk collection, cultivation of root crops and grain-bearing plants, maintenance of fruit trees, multipurpose home gardens, and slash-and-burn techniques for larger cleared plots – are continued in the Late Ceramic with their intensification noted at least for certain areas in the Greater Antilles. Intensification has been related to changing climates, population expansion, and

sociopolitical pressures to which can be added increased demands for foods and special-purpose plants related to public feasting, ceremonies, and health/spiritual concerns.

The latter is indicated by the expanded "Other Uses" section of Table 4. Several health-related plants have been added, along with those producing red and black dyes and beverages. Ethnohistoric sources indicate that home gardens were used to cultivate a significant number of herbs, medicinal plants, and those for magico-ritual purposes. It has been suggested that shamans or other specialists oversaw the growing of such special-purpose plants in home gardens or otherwise specialized plots since they would have had the requisite knowledge regarding their use and purposes. Tobacco was used both for social smoking and, along with *cohoba*, ritual occasions. The latter compound was made from ground seeds from the genus *Anadenanthera* trees mixed with crushed shell or lime to form a psychotropic drug that was inhaled or snuffed through the nostrils. The resulting ecstatic-visionary trances allowed the shaman to interact with cemí spirits to affect desired social outcomes and healing states. The red and black dyes in addition to decorative functions may have been employed in magico-rituals and curative practices (Newsom 2008: 174–179, 188; Reid et al. 2018: 214–215, 217).

Agricultural intensification rested not on the significant addition of new wild or domesticated plants, but on practices to increase yields. Reconstructed practices included the construction of *montones*, semipermanent mounds used for the growing of especially manioc and sweet potatoes. A matrix or mounding of loose dirt concentrated organic materials providing for faster growth and larger tubers. They were constructed within or supplemental to swidden agricultural plots termed *conucos*, as well as along river flood plains. *Montones* measured 1 m high by 3 m in diameter with flat tops. Manioc is a particularly desirable root crop in that it can grow in all soil types, is draught resistant, has a high caloric content, matures in 10 months, and can be stored up to 3 years before harvesting. Terracing was noted at the end of the Early Ceramic for Puerto Rico, with more locations documented in the Late Ceramic. *Montone* and terracing construction has also been reported from Cuba and Hispaniola (Reid et al. 2018: 216–218).

Settlement

Settlement patterns of this period are marked by an increase in the number and type of sites, ranking or a differential ordering by size and location, diverse internal village and house arrangements, occupation of new areas, and the development at certain sites and areas of enclosures or formally demarcated spaces with earthen or stone alignments. A growing population is indicated, although this trend may not have been uniform across the region or time period. After around AD 1200, a leveling-off or even decrease is suggested for Puerto Rico, decrease and site abandonment for many of the northern Leewards, but the opposite in the Windwards with settlement density highest at the end of the prehistoric period (Bright 2011: 239–240; Hofman 2013: 208–212 Keegan and Hofman 2017: 96–97, 106–107, 215, 229, 238).

On Puerto Rico, the Early Ceramic pattern of large, relatively autonomous villages located in coastal settings transitions to settlements situated in the foothills and mountainous interior on agriculturally suitable river terraces. Whether derived from fissioned parent communities or unrelated populations, the settlements represent small villages (under three hectares) or hamlets composed of nuclear families judging from the extant limited number of excavated houses that average 8 m in diameter. This dispersed pattern of small settlements linked to others in clusters is allied to the establishment of some new large coastal villages, as well as the continued occupation of Early Ceramic ones. Midden arrangements are variable. Circular patterns continue at various sites, while sheet, hillside, and no directly associated middens are also recorded (Keegan and Hofman 2017: 89–91, 96–99, 107; Rodríguez Ramos 2010: 156–157, 159–160).

On Hispaniola which it should be remembered did not have prior Saladoid occupation, a wide range of settlements is reported including large and small villages, hamlets, homesteads, and special-purpose locations. Like Puerto Rico,

sites are distributed among coastal and interior areas to take advantage of available resources involving those near mangroves and rich marine environments and inland locations for arable lands. For the Dominican portion of the island, large houses of some 30–40 people likely sheltering extended families situated around a cleared central plaza with a ring-shaped midden totaling 500 individuals is reported for Juanpedro (AD 840–1300), while smaller houses arranged in six clusters of from 30 to 40 people per cluster possibly representing clan or lineage compounds is documented for El Cabo (AD 600–1500) making for approximately half the population of Juanpedro. Work huts, windbreaks and fences were also noted at El Cabo (Keegan and Hofman 2017: 122–128).

The site of El Flaco (AD 900–1500), also in the Dominican Republic, exemplifies a number of villages that in addition to house structures possess multi-use mounds and earthworks. The smaller-scale houses exhibit a double row of alternating large and small posts built on leveled platforms that are enclosed by several mounds and earthen walls. The mounds' involved stratigraphy reflects different uses from refuse deposits to burials. Special-purpose sites include Îl à Rat in Haiti (ca. AD 900–1500) that likely served as an exporter of fish and marine proteins, especially conch, to interior settlements. The site is located amid extensive coral reefs, seagrass beds, and a lagoon. Fish bones and conch shells far exceed the estimated needs of a small village. Special production sites involving a range of items (e.g., marine foodstuffs, cotton, salt) have also been noted for Puerto Rico, Cuba, the southern Bahamas, and the Lesser Antilles as outlined below (Keegan and Hofman 2017: 107, 128–134, 167).

The Ceramic period in Cuba, like that of Hispaniola, does not begin until Ostionoid, Meillacoid, and Chicoid pottery-producing groups arrive at different times and from multi-proposed Caribbean locations. These Late Ceramic farmers/fishermen primarily established communities in the eastern and central portion of the island; Meillacoid settlements predominate. Interactions among the new settlers and resident Archaic groups yielded what has been characterized as a series of distinct cultural identities marked by variable material traits, sociopolitical developments, economic relationships, and settlement arrangements.

A study of Meillacoid-identified occupations in southeast Cuba indicated three site types: coastal exploitation zones, small short-term farmsteads for agricultural or fishing pursuits, and different sized habitation locations, the majority encompassing 30–40 m. A high degree of stability in subsistence and material culture patterns is suggested even amid apparent population increase. Evidence for coastal-inland exchanges of food resources is also suggested.

Another investigation of Meillacoid settlements in the Maniabon Hills area of northeastern Cuba identified 190 sites or zones of which 97 possessed enough data for further analyses. Apart from 13 Archaic coastal shell deposits, settlements were classified into 2 village types: coastal fishing occupations of from 2 to 10 middens with largely shell remains and larger inland villages ($n = 74$) with regular habitation-related refuse. They were all located on nearby hilltops usually 4 km from, and overlooking the sea, apparently selected for access to arable land and freshwater resources. These inland settlements, like those of Jamaica (see below) and areas on Hispaniola, lined the hill sides averaging 2500 m^2 in size enclosing five to ten mounds. The variability observed in the numbers per site, shapes, and arrangements of these deep midden mounds again likely reflects a variety of functions from functional to ritual (Keegan and Hofman 2017: 155–159, 169).

In the previous Lithic/Archaic and Early Ceramic periods, the dominant migration issue concerned large-scale in-migration from continental zones. In the Late Ceramic, the dominant issue involves intra-regional settlement of already occupied islands by expanding on-island or new off-island populations as just noted, in addition to the permanent occupation of the remaining large Greater Antillean islands of the Bahamas and Jamaica. Multiple and partially overlapping settlement efforts are inferred for the Bahamas. The first effort begins around AD 700 by Ostionoid and Meillacoid groups from Hispaniola or Puerto

Rico that are ultimately unsuccessful. The sites are classified as recurrently occupied special extraction sites, camps, and villages strategically located to maximize the exploitation of marine resources and shell for bead making. These colony-like locations of the southern Bahamian Turks and Caicos area likely exported conch meat, fish, and finished shell beads to home communities.

The southern sites around AD 1300 are abandoned, in part perhaps due to the growing influence of northern groups that settled the center of the Bahamian archipelago in the AD 700/800s. These horticultural fisher-collectors or Early Lucayans probably came from northern Cuba and managed to establish permanent occupation and a local ceramic tradition – Palmetto. Although continuous occupation was achieved, sites are small with shallow middens and low artifact densities indicating frequent village relocations of probably extended families or lineage segments. The high degree of mobility observed for the Early Lucayan phase continues into the Late Phase AD 1100–1530+, albeit with longer-term residence suggested. Cave, burial, and special-purpose sites can be added as settlement types; all are located along the coasts with the open-air residential settlements usually situated atop sand dunes in a linear arrangement of structures. Occupation is noted throughout the archipelago, although it is unclear if settlement expansion is due to population increase, restructuring, or their combination. Trade in raw and finished goods that begun during the non-Lucayan period continues and expands with the importation of such goods as greenstone, petaloid axes, and copper from, and the export of items including salt, salted fish, cotton, and parrots to Cuba and Hispaniola (Berman et al. 2013: 264–269; Keegan and Hofman 2017: 181–186).

Jamaica, like the Bahamas, also experienced two separate successful colonization efforts. Limited excavations from the initial attempt or Little River phase (AD 550–950) demonstrate a preference for coastal settlements and a reliance on marine protein sources involving fishes, mollusks, and in particular sea turtles. Their shallow deposits point to short-term occupations as base camps for particular resource exploitation. These Ostionoid pottery-producing groups are shortly succeeded by those making Meillacoid ceramics. Settlements of the White Marl period exhibit deeper deposits suggesting long-term occupation with sites frequently located on hilltops/hillsides overlooking the coasts. Inland occupations are also recorded, as are large villages with midden mounds and central open spaces. All available environments were exploited, focusing on local resources and presenting a pattern of greater reliance on cultivated foodstuffs and freshwater taxa for inland sites compared to a greater reliance on marine species for coastal locations (Keegan and Hofman 2017: 189–195; Wesler 2013).

An increase in the number, size, variety, and ranking of settlements is also observed at the beginning of the Late Ceramic (AD 600–800) in the entire Lesser Antilles. Coastal locations continue along with new inland villages and hamlets situated near rivers, as elsewhere in the region to take advantage of arable land and freshwater/terrestrial resources. Previously uninhabited islands are now colonized or regularly visited for particular raw materials and food sources, as well as special activities and ceremonies including islets, cays, promontories, and open-air/cave sites with rock art. The observed internal arrangement of habitation sites includes a living area and open space/plaza encircled by a doughnut-shaped refuse midden.

Around AD 1200/1300, however, a significant decrease in the number and size of settlements is documented for the northern Lesser Antilles involving a shift from large permanent settlements to those in more strategic and defensive locations. This trend stands in contrast to continued high site densities for the southern or windward islands. The difference in trajectories has been linked to changing sociopolitical structures (see section below) where the northern defensive locations are viewed as ports-of-trade, new colonization efforts and lookout posts for societies that have become increasing integrated into the Greater Antillean complex sociopolitical sphere. This area, local Lesser Antillean communities and northern South American appear to be interconnected via material and ideological

Caribbean Prehistoric Archaeology, Fig. 11 (**a**) West alignment of main square enclosure at Caguana, Puerto Rico. (**b**) One of the alignment boulders with complex head petroglyph. (Courtesy of Michael A. Cinquino)

culture exchanges, within it appears a strong competitive context (Bright 2011: 239–240; Hofman 2013: 208–212; Keegan and Hofman 2017: 215, 229, 238).

Enclosures, variously termed *bateys*, precincts, ballcourts, and plazas, are first detected archaeologically at the beginning of the Late Ceramic with increasing numbers after AD 1000 in the Greater Antilles. They represent formally demarked level spaces wholly or partially outlined with stone or earthen structural elements that are fixed open places in the landscape. Precincts are important in their own right as research topics that is more than matched by their incorporation as one data point employed to reconstruct Late Ceramic social, political, religious, and economic life as the following sections demonstrate.

The structures differ in size, shape, location, construction details, presence of rock art, and iconography. Many are rectangular, with square, oval, circular, and other shapes recorded. Sizes range from under 100 m^2 up to 43,000 m^2 for the largest example in the region (Corral de los Indios in the Dominican Republic). Single lines of upright earth-embedded boulders, normally a meter or less in height, represent the most frequent alignment type, followed by earthen embankments, outlined depressions, and stone/earth combinations. Distribution is uneven within the region. Puerto Rico registers the highest number with some 200 single and multiple plazas; Hispaniola in the twenties and fewer still for Cuba, the Bahamas, and the Virgin Islands. They appear to be lacking in the remaining Antilles.

Puerto Rico possesses several multiple enclosures, most notably Caguana (Fig. 11a, b) in the west central highlands that registers the most precincts per site in the region with a total of 12 extant elements: one stone platform, nine rectangular and one oval boulder-lined courts, and the largest, central square plaza with a stone boulder and pavement arrangement. Most of the surviving petroglyphs are found on the interiors of the square plaza's west wall. The precinct construction has been dated to AD 1300–1450 enclosing some 5500 m^2. Jácana represents one of the island's single precinct sites with ae large 2000-m^2 stone-lined square plaza exhibiting boulders on all four sides with some 62 petroglyphs on at least three sides. The site is located in the southern foothills with the enclosure dating to AD 1300–1300. Minimal domestic activity is indicated for both sites.

In contrast, Hispaniola and Cuba exhibit lower location numbers but significantly larger enclosures. Corral de los Indios's central oval plaza in the northwest Dominican Republic demarcates with a single-wide, raised cobblestone platform some 43,000 m^2 in area. A single monolith with a

humanlike facial petroglyph was reported in the center that also had one or more causeways leading to a nearby river, with a substantial petroglyph assemblage. This plaza represents an enlarged village center that has been identified ethnohistorically with Caonabo, the most powerful chief on the island.

Enclosures occur as integral elements in habitation sites, in addition to inter-village non--habitation locations as single or multiple courts. In habitation sites they represent transformed Early Ceramic open public spaces into newly bounded ones; not all (and maybe a minority) settlements undertook such conversions or can necessarily be linked to particular non-village precinct sites. It seems they were multifunctional – secular, religious, theatrical, economic, social, and political – and multi-scalar, sub-village, small and large villages, inter-village, subregion, and regional. Communal social and ceremonial activities related to more local concerns like marriages, births, and age/sex passage rites involving limited audiences and participants likely played out at smaller village enclosures. Activities would have been amplified in terms of needed resources, impact, and participant/audience engagement at larger village and inter-community precincts.

Ethnohistoric sources concerning Greater Antillean groups indicate certain possibilities for the amplified category including playing a ball game with a solid rubber ball, complete with betting and ritual aspects, as well as *areytos* that entailed recitals and performances of chiefly, group, and religious histories. They were accompanied by drinking, feasting, and mock battles that probably differed according to specific occasions such as times of natural disasters and deaths of chiefs (Keegan and Hofman 2017: 99–103, 108, 141–143; Hayward and Cinquino 2012; Hayward et al. 2013; Oliver 2005; Wilson 2007: 114–136).

Sociopolitical Organization

The intensification of sociopolitical structures in the Late Ceramic involves transitioning from prior relatively unranked and autonomous communities to at least two-tiered stratified societies of elites and commoners incorporated into simple to complex chiefdoms by the time of European contact. These developments were not uniform within the region. Puerto Rico and Hispaniola present the clearest evidence for complex chiefdom development, less stratified and expansive structures for the rest of the northern Caribbean, and in contrast, a strong continuity with the previous sociopolitical landscape in the southern Lesser Antilles. Further a range of integration is indicated from still autonomous Lithic/Archaic societies argued for western Cuba (see Table 2c) to unincorporated groups and interaction spheres like the southern Lesser Antilles linked nonetheless via multilevel/multi-item exchange systems to full incorporation in complex polities via elite marriages/sponsored trade, political alliances, and direct control. Various formal models for these changes have been proposed, two of which are outlined here: competitive expansion and peer polity.

Siegel (1999) has advanced the competitive expansion model for specifically Puerto Rico that centers on the implications of the shift from the informal Early Ceramic public spaces to their formal delineation in the Late Ceramic outlined above. He sees the early period settlement centers as ritually changed spaces frequently serving as places for the burial of community members with shamans primarily in charge of associated rituals and more secular activities. Formal delineation suggests both a continuance with past ideology and settlement structure and significant departures including the emergence of certain individuals and kin groups – chiefs, related individuals or elites, and lineages – as the new directors of communal activities. These events increasingly focus on the chiefs and elites as mediators between the people and spirit world with the accompanying elevation of their ancestors as active participants in maintaining the public well-being. It was the elites who maintained control over ceremonial space activities directed at political affairs from the local village to supra-village level, relegating the shamans to presiding over religious affairs at the private lower community sphere. Siegel reasons that if enclosures reflect a continuum of influence consolidation from unrestrictive to selective groups and individuals, then their changes through time should correlate with

political developments. Employing precinct data from Puerto Rico, he concludes that the island registers between four and six relatively equal power centers by AD 1200.

Siegel's model envisions enclosures as places for contesting prestige and influence that are hierarchically ordered (polities with supporting centers). In the peer-polity model, proposed by several researchers (see Curet et al. 2004; Wilson 2007), Puerto Rico's increasing political complexity is seen as deriving from a number of different, though comparable, processes. These include local environmental conditions and resources, diverse historical contexts, and individual chiefly ideological and political strategies. The polities are small-scale and nearly equal that develop within networks of communication among different groups or peer-polity interactions. They tend to be short-lived, a condition noted for chiefdoms in general, since critical network relationships can be disrupted by the perceived loss of spiritual/*cemí* support or death of an influential chief leading to ready collapse.

Enclosures can also be seen as places of social activity and identity formation (Curet and Torres 2010; Torres 2010). The proposed activities suggested for enclosures and settlement centers would have promoted a sense of belonging and attachment. In this viewpoint, hierarchies and political power result from community consensus that validates group identity, as well as the creation of powerful individuals and social inequalities. Elites and commoners both gain from such arrangements where the acknowledged elevated influence and authority of the elite is returned to the community in the form of material, spiritual, and social well-being. This process of social formation and identity was continual, where relationships were negotiated and recreated through the variety of secular and religious events at enclosures and settlement centers.

Descriptions of Caribbean chiefdoms or *cacicazgos* rely heavily on ethnohistorial accounts of Greater Antillean Taíno groups at contact, particularly those of Hispaniola and Puerto Rico. Variability in structural organization is certainly indicated. Five major *cacicazgos* on Hispaniola are reported organized under a three-level system of paramount chiefs or *caciques*, regional chiefs controlling allied village, and individual village leaders. Puerto Rico, in contrast, is reported to have had 17 chiefs suggesting authority over smaller territories and a simpler arrangement of regional *caciques* supported by local village heads.

Chiefly control at any level rested on the ability to interact with the *cemí* spirits, to attract supporters, and to maintain the allegiance of the commoners who made up the majority of the population. Their roles included mobilization for agricultural labor and military service, redistribution of food and goods in life and death during *areitos*, organizing and composing new elements for *areito* performances, and directing the production and trade of sumptuary items, as well as esoteric knowledge. Chiefs were assisted in their responsibilities by other high-ranking peoples and relatives. Shamans or *behiques*, chiefs, and the elite ritually communicated with *cemís* with apparently divergent goals: individual physical-spiritual health versus guidance regarding public political concerns (Keegan and Hofman 2017: 112–113, 252–253; Oliver 2005: 237, 241–245; Sued-Badillo 2007: 259–274; Wilson 2007).

Elsewhere in the Caribbean sociopolitical structures represent a complex interplay of local to regional influences. For example, as already noted societies on Cuba have been characterized as exhibiting highly individualized expressions. Lithic/Archaic Age communities it seems accommodated in-migrating Ostionoid, Meillacoid, and Chicoid groups resulting in a variety of corresponding structural arrangements from tribal to chiefdoms. Chicoid sites are concentrated in northeast Cuba including four large plazas like those of the Dominican Republic, but instead bounded by earthen embankments not stone boulders or pavements. The presence of these plazas and their differences in construction point to populations organized at a chiefdom level derived from local developments and not direct control or integration into the complex chiefdoms of Hispaniola (Keegan and Hofman 2017: 165–167, 169; Wilson 2007: 130–133).

Parallel or different local factors are indicated in the emergence of regional-level integration

argued for the Banes region in the Maniabon Hills, discussed under the foregoing "Settlement" section. Further examination of the Meillacoid settlements begun around AD 1100 reveals that the hilltop locations are socially isolated from one another by large open spaces composed of larger centers with smaller surrounding satellite communities usually within 5 km. Four such clusters have been proposed with the settlement pattern demonstrating a high degree of cultural continuity up to and into the Colonial period. Ritual or high status objects such as wooden duhos and stone/shell beads and pendants characterized the centers. These stable interacting discrete center-satellite evenly spaced clusters have additionally been interpreted as two-tiered social and political hierarchies or simple chiefdoms (Keegan and Hofman 2017: 160–162).

In the Lesser Antilles, opposing sociopolitical trajectories are indicated. Initially a continuation of the Saladoid complex tribal arrangement based on individual personal abilities (Big Man model) or lineage-based hierarchies is indicated. Localized interaction spheres also continue involving control over the production and distribution of goods, along with the establishment of alliance networks, marriage agreements, and larger political units. In the northern section, the political centers might have operated as peer-polities linking multiple settlement or islands. At certain sites, highly valued items and complex mortuary practices point to social differentiation or stratification. The polities maintained local, micro- and macro-regional exchange networks with Caribbean and mainland areas.

After AD 1200/1300 significant settlement and sociopolitical reorientation is apparent. Greater Antillean complex chiefdoms incorporate or extend their influence into the northern Lesser Antilles, while northern South American influence increases in the southern Lesser Antilles. These influences appear to have been more negative in the north with population decline, displacement, and changed settlement types (see "Settlement" section above) documented versus the maintenance of internal social cohesion in the south (Hofman 2013: 206–207, 214–216; Keegan and Hofman 2017: 224–226, 238).

For the southern Lesser Antilles, local integration of largely autonomous self-sufficient communities comprises the political landscape with strong inter-island ties, as well as inter-regional ones, albeit in an apparent competitive atmosphere. An even or regular site distribution pattern is registered with locations in similar environments exploiting resources in similar ways. Settings include coastal fringes, mountains, reefs, freshwater sources (rivers, springs, rainwater), and inland for the exploitation of cultigens, wild plant materials, as well as marine and terrestrial animal protein resources (Boomert 2013; Bright 2011).

Ideology

Two aspects of Late Ceramic religious development are considered here: the significant increase in the numbers, location, and image complexity of rock art and the nature of religious organization (see Table 5). A substantial body of rock art sites is now distributed throughout the region. Petroglyphs or carved images and pictographs or painted designs are found on varied rock surfaces from the stones aligning enclosures, to boulders along waterways, to cave walls and inland formations. While zoomorphic (naturalistic and stylized fishes, birds, turtles), geometric (circles, spirals), and abstract (arrangements of straight, curvilinear lines and dots) motifs are recorded, a marked emphasis on anthropomorphic figures is evident. They include simple (outlined heads with eyes and mouths) to complex (addition of such elements as ears, headdresses, noses) humanlike faces that frequently lack even minimally depicted body forms (shoulder outline, stick figures) (see Fig. 11b). A minor number, like those at Caguana and Jàcana, are more fully rendered with complex heads, bodies, legs, arms, digits, and gender indications.

Spatial distributions are uneven. For instance, rock art is found on all the major islands of the Greater Antilles, while sites are normally only located on the larger islands of the Lesser Antilles. Image numbers in the region range from a few to the low hundreds for petroglyphs and into the low thousands for pictographs. Formal dating models have been proposed that suggest a

division into Lithic/Archaic, Ceramic, and early Historic periods with primary production in the Ceramic Age. Ethnohistoric and ethnographic sources form the basis for interpreting the meaning and function of the images. Interpretations range from simple identification of the forms and cross-site stylistic comparisons to detailed constructs involving cosmological and political aspects (Hayward et al. 2009b). For example, the petroglyphs at Caguana may represent the materialization of the cosmic order and are seen as stand-ins for chiefly ancestors or *cemí* substitutes and as visual referents that reinforce chiefly and elite influence and legitimacy (Oliver 2005).

Rock art has also been employed to argue for increasing formal religious structure. One expectation of a low level of religious organization should be a low degree of visual redundancy in associated material correlates, in this case rock art, and a higher degree in more centralized systems. A small sample of rock art assemblages indicated a low but shifting degree of visual redundancy suggesting that efforts to more formally structure the religious organization may have been taking place in concert with the increasing stratification just noted in the sociopolitical sphere. Evidence for the shift may be seen in the frequent and prominent use of at least one design layout, that of a circle with an internal dot flanked by triangles, that cross-cuts a number of media from rock art to the carved stone collars, large three-pointers, and elbow stones, as well as Chican ceramics. Increasing restructuring by the elite might have been complementary to existing ideologies, rather than displacement, since small three-pointers linked as far back as Lithic/Archaic times continue to be produced (see also Keegan and Hofman 2017 and Rodríguez Ramos 2010, among others for similar structural change assessments).

Final Considerations

The unfolding of Caribbean prehistory in this essay has traced a complex development once seen as relatively straightforward as indicated in the following flow chart:

. . . once seen as relatively straightforward. Groups from northeast South American diversify into Lithic/Archaic societies then Saladoid ones and finally the several Taino populations at contact in the northern Caribbean. In this model, Huecans are part of the Saladoid and Lithic/Archaic groups have died out or been absorbed. Mainland lies are minimized. A closer examination indicates a more involved history of migrating and interacting groups.

In this viewpoint groups derive from various mainland areas of at least northern South America and lower Central America that establish insular identities, interact with each other and the mainland that by the end of the prehistoric period are characterized by a plurality of societies that though they differ in localized expressions (settlement systems, sociopolitical structures, material culture, rock art) are nonetheless Caribbean cultures.

Caribbean Rock Art

Michele H. Hayward and Michael A. Cinquino
Panamerican Consultants, Inc., Buffalo, NY, USA

Introduction

Rock art was being produced by some of the earliest groups moving into the Caribbean island arc from either or both Central and South American coastal regions. For this discussion the region includes the Bahamian archipelago, Cuba, Hispaniola (modern nations of Haiti and Dominican Republic), Jamaica, Puerto Rico, and the Virgin Islands of the northern Greater Antilles; the southern Lesser Antilles extends from Sombrero and Anguilla in the north to Grenada in the south, as well as the Venezuela offshore islands of Trinidad, Tobago, Aruba, Bonaire, and Curaçao (Hayward et al. 2009a: 3–6).

The prehistoric population history of the area is witness to major and minor in-migrating groups from nearby mainlands, a settling-in period to new island environmental and cultural settings, and the development of exchange networks and interaction spheres within the region along with maintenance of ties with continental populations. The period ends with the arrival ca. 1500 of the Spanish that within decades results in the depopulation and displacement of the Amerindians with their largely subsequent replacement by different European and African slave groups.

Irving Rouse's 1992 chronological framework for Caribbean prehistory remains a standard one, albeit in the updated version employed herein. Three broad periods are recognized: the Preceramic, Ceramic, and Contact or Early Historic. The Preceramic encompasses two subperiods, the Lithic and Archaic ages from 7500/4000 to 400/250 B.C., characterized by the manufacture of flaked and ground stone tools; organization into small, mobile, and independent groups; varied subsistence practices incorporating hunting of land animals, exploitation of marine and riverine resources and manipulation of plant foods, in addition to minor production of pottery (Hayward et al. 2009a: 6–9).

The Ceramic Period is likewise divided into two subperiods: Early, 400/250 B. C to A.D. 600, and Late, A.D. 600–1500. This period is marked by increased sociopolitical complexity, widespread adaption of ceramic production, full-time horticulture, permanent village settlements, and population growth. In the Greater Antilles, early tribal political organization transforms into simple and complex chiefdoms by European

Contact with at least a two-tiered division of societies into elites and commoners. The Late Ceramic indigenous groups in the Greater Antilles are the direct ancestors of the contact or historic-period Taíno groups that Europeans encountered and reported on, producing valuable material on native cultural and religious systems (Hayward et al. 2009a: 9–12). Similarly, European-authored descriptions of culturally diverse Lesser Antillean indigenous groups are also extant.

Definitions

The overwhelming majority of the rock art is of precontact date; limited production of images by native groups and African populations into the historic period is apparent at several locations in the Greater Antilles (Gutiérrez Calvache et al. 2014; Hayward et al. 2009b; López Belando 2009: 17).

The region's rock art takes three forms. Petroglyphs refer to carved, pecked, ground, or other agency-produced designs; pictographs (rock paintings) represent painted or drawn images; and rock sculptures. The first two categories are found on immovable or relatively stationary natural rock art surfaces, while the third class covers portable items such as small to large triangular-shaped artifacts and small freestanding statues. Historically, the portable stone objects have not been analyzed as rock art but instead are considered with artifact classes of similar manufacture or function. For instance, the freestanding stone statues of largely anthropomorphic design are examined in conjunction with those made of wood, perishable materials, or specially preserved human skeletal remains. Geoglyphs and large-scale rock arrangements remain unreported from the area prehistorically; small-scale layouts for say astronomical observations may have been undertaken (Hayward et al. 2009a: 2, 11).

Two salient features of Caribbean precontact rock art involve an emphasis on human-like facial and facial/body forms and a high degree of site variability. Image-makers appear to have chosen design elements, motifs, and arrangement styles from a common repertoire to create rock art for specific times, places, and activities (Hayward et al. 2012).

Survey and Documentation Status

Characterizations of images and sites are ongoing since systematic site surveys and documentation efforts for the area remain incomplete. Substantial areas of the larger islands of the Greater Antilles have not been examined, while the survey status for the Lesser Antilles varies widely from island to island. Sites continue to be located on a continuing basis. Recording of site data varies from simple mention in the literature or institutional database, to well-documented individual and multiple-site locations, and to site registries at different subregional geographical or administrative levels. No regional database has been elaborated (Roe 2009: 199–204).

Image Classification and Distributions

The images are generally classified according to variants of a fourfold typology – anthropomorphs, zoomorphs, geometric designs, and abstract motifs – with petroglyphs and pictographs normally grouped together for such considerations. The majority of anthropomorphs consist of simple to complex faces (Fig. 1a, b); less frequent are facial images accompanied by different body designs Fig. 2). Groupings of two to three pits or dashes are considered to represent human-like faces that can have no, partial or fully enclosing shapes (round, ovoid, heart-shaped). Complex faces involve the addition of varied internal and external design elements such as eyebrows, noses, ears, and rays above and below the face, as well as a range of headdresses including tabular, linear, crowns, and projections. Double or multiple encircled facial motifs are present, as are interconnected facial arrangements. Attached body motifs range from upper body outlines to different forms (rectangular, ovoid) with varied internal layouts of pits, dashes, and lines. Lineal, outlined, or digited arms, hands, legs, and feet are infrequently added to anthropomorphs, as are

Las Caritas, Independencia, Dominican Republic. (Courtesy Glenis Tavarez María; photographer Renato Rimoli 2016)

gender indications. Handprints though executed are rare (Hayward et al. 2009b).

Readily identifiable zoomorphs include turtles, diverse birds and fishes, iguanas, bats, owls, spiders, and snakes (Fig. 3). They are often rendered realistically allowing for suggested specific taxa identifications. Spirals, crosses, and circles are among the geometric designs, while varied orders of curved and straight lines, pits, dashes, and other elements account for abstract or non-readily interpreted motifs to the modern Westerner (Fig. 4a, b; Hayward et al. 2009b).

Petroglyphs and pictographs were executed at four principal locations in the Caribbean: cave and rock shelter walls, ceilings, and speleothems; boulders along waterways or at other types of water resources such as pools and springs; rock formations at island interiors and coastal fringes; and ball courts/plazas or enclosures. The later represent level earthen surfaces bordered wholly or in part by earthen/rock embankments or upright slabs frequently with petroglyphs. They are interpreted as communal spaces for a range of intersecting activities from the sociopolitical to grand theater to religious. Image totals per site generally vary from one to the low hundreds for petroglyphs and up to the low thousands for pictographs (Roe 2009: 205, 207, 208–211).

Rock art spatial distributions are unequal. For example, petroglyphs and pictographs are found on all the major islands of the Greater Antilles and at all four principal locations where petroglyph sites outnumber pictograph ones except for Cuba. In contrast the larger Lesser Antillean islands tend to possess rock art, while the smaller ones do not. Petroglyphs are exclusive or nearly so throughout the Lesser Antilles, as well as the Greater Antillean Virgin Islands, with pictographs heavily predominating on Aruba, Bonaire, and Curaçao. Rock art outside of the Greater Antilles

occurs at only three of the four principal locations since rock/earthen lined enclosures have not been reliably reported from this region (Roe 2009: 200–205, 209, 211–213).

Dating

Chronological control of the region's rock art primarily rests on cross-datable associations with at-site materials, nearby archeological sites, and similarly rendered assemblages. A minor number of directly dated images from pictograph components, along with several proposed single to multiple island sequences, complement available data sources. Although this database is limited, certain statements concerning Caribbean rock art development are apparent: (1) rock art can be grouped into Preceramic, Ceramic, and Historic traditions; (2) the Ceramic is the principal period of production; (3) production may be discontinuous in several areas of the Lesser and Greater Antilles with an absence or time-lag suggested during most of the Early Ceramic; (4) particular rock art design and distributional patterns may well relate to sociopolitical and religious spatiotemporal trends; and (5) an increase over time is apparent in overall size, design element complexity, and compositional arrangements (Roe 2009; Hayward et al. 2014).

Interpretation

Researchers normally rely on three data sources to propose the meaning and functions of prehistoric Caribbean rock art: ethnohistoric narratives of native lifeways at or near the contact period,

Caribbean Rock Art, Fig. 4 (**a**) Spiral petroglyph. Anamuyita Site in Altagracia Province, Dominican Republic. (Courtesy Glenis Tavarez María; photographer Odalis Rosado 2009). (**b**) Abstract ordering of lines and pits petroglyph. Anamuyita Site in Altagracia Province, Dominican Republic. (Courtesy Glenis Tavarez María; photographer Odalis Rosado 2013)

ethnographic analogies from the culturally related lowland South American indigenous groups, and theoretical frameworks including structuralism, cognitive archaeology, and agency theory. The first two sources provide the foundation for the commonly viewed assumption that the rock art primarily functions in the religious realm where interpretations frequently tie images to particular reconstructed myth themes and personages, as well as general cosmological and religious principles. Alternative nonreligious or intersecting religious/other cultural subsystem functions have been advanced concerning use as territorial markers, as aides in astronomical observations, and as visual referents messaging political elite control or co-control with religious leaders over the supernatural world and forces.

Interpretive efforts encompass a single to few figures, the same category of images found in different locations, all the petroglyphs or pictographs at a single site or similar ones, and the region's rock art in general. The following two examples include an argument for the function of rock art in general and the interpretation of the Mural de Zamas petroglyph assemblage as representing the daily celestial round.

Drawing upon a structuralist approach, as well as ethnohistoric and ethnographic accounts, Petitjean Roget (2011) contends that the regulation of mythic or actual weather extremes is the general purpose of rock art. The location of the images determines which extremes are involved. South American oral traditions make mention of drought and floods, "burnt and drowned worlds," respectively. Petroglyphs found near water sources would be seen as guardians that protect humans from too much water (floods) and too little (droughts) water, droughts, a consideration of importance to precontact horticultural groups in the region. Ethnohistoric sources indicate caves

were sacred or symbolic places of contact between the tri-parte cosmos of the present earthly plane, the spirit-filled sky, and the underworld. They also had womb-like or life-giving connotations. Rock art located at the entrances would therefore be a focal point of multiple opposites including the male and dry exterior versus the feminine and humid interior. Petroglyphs at enclosures denote a boundary between the interior sacred space of the ball court/plaza and the surrounding profane village area. Images at island coastal zones separate the dry world of the earth from the wet world of the sea. One recorded myth, for instance, describes the sea being created by a deluge of water from a gourd; in this case the rock art guards against a repeat of waters that in the mythic past swamped the island world.

The Mural de Zamas rock art site is located in the mountains of west-central Puerto Rico, with some 49 petroglyphs carved into the rock shelter's opening. Key to Roe's (one of the authors) (2017) interpretation of the assemblage as a microcosmic representation of the macrocosmic diurnal-nocturnal cycle is the identification of certain images associated with day and night, as well as their relative positioning (Fig. 5). Amid an eastern grouping of largely simple to complex human-like faces indicated by roundish heads/pits or dashes for eyes/additional attached design elements (head projections, ears, and rays) are two completely rayed facial motifs and an encircled-eyed face with two pointy head projections. Roe considers the rayed images to represent sun symbols, a reasonable assumption for modern Westerners, yet he adds that various South American natives also configure the sun as a circle with radially arranged rayed eminences. The pointy head Roe identifies as the Puerto Rican screech owl, which normally calls at dawn. The middle grouping contains another sun image this time with six rounded internal-dot projections surrounding the pitted eye and enclosed mouth divided face. Two large complex faces with ears and elongated head crowns, along with two smaller similarly rendered faces, complete the grouping. A number of simple to complex faces make up the western grouping in addition to night-associated images of a coiled snake (Puerto Rican boas wait in trees at bat locations), prominent rays encircling a very small face suggesting a possible star, two snout-like faces with small mouths and

Caribbean Rock Art, Fig. 5 Proposed depiction of the daily celestial cycle with certain petroglyphs representing the day to night transition, Mural de Zamas, Puerto Rico (Hernández Llanes et al. 2017: Fig. 27)

ear/head projections that resemble island nighttime insectivores, and finally a probable bat motif with encircled eyes and prominent ears that rise above the head on either side. Roe argues that rock art assemblages should be considered in their entirety, as intersecting parts of a whole. At Mural de Zamas therefore the images can be seen as more than a disjoined collection of images; they form a narrative of the easterly daily sun rising and midday passage followed by its setting in the west and replacement by night.

Prehistoric rock art even continues to play a role in the religious practices, as well as the identity and economics of the region's present societies. Researchers have noted the incorporation of certain rock art sites and images as places and objects of devotion or as part of a yearly pilgrimage round, for instance in the Dominican Republic, for instance. Investigators have also explored the use of petroglyphs and pictographs to symbolically reinforce the commonly promoted tripartite native Amerindian alongside European- and African-derived cultural contributions to the modern populations of Puerto Rico and the Dominican Republic. The use of rock art motifs in public monuments, local handicrafts, and fine art is noteworthy in various locations in the Caribbean.

Carman, John

Mary-Catherine Garden
Archaeological Services Inc, Toronto, ON, Canada

Basic Biographical Information

Dr. John Carman, known best for his work with historic battlefields, is among the prominent researchers who have focused on the notion of "value" within the context of heritage studies. Coming to heritage studies via archaeology and an early career in management, his earliest work explored value with particular references to English law (Carman 1996). In addition to his work with historic battlefields, he has a wide-ranging set of research interests within heritage which include public interpretation, the public, and ownership, and which are all anchored by his interest in value. This work has resulted in an extensive list of publications and his journal articles are to be found in subject areas including conflict studies, public archaeology, and museum studies.

John Carman's early training as an archaeologist began at the University of London and later continued his academic training in the Department of Archaeology, Cambridge University, where he received an M.Phil. (1989) and Ph.D. (1993) in heritage studies. Since then, his interest in value has been married to practical and theoretical explorations in public interpretation, commemoration, and the marking of heritage sites. These interests have been refined into a long-term investigation of landscape of battlefields. His *Bloody Meadow*s project undertaken with Patricia Carman (Carman and Carman 2006) represents more than a decade of focused research into the heritage of battlefields and explores these landscapes as heritage objects. Since 2005, he has held the post of University Fellow and Senior Lecturer in Heritage Valuation in the Institute of Archaeology and Antiquity, Birmingham University.

John Carman's career and his scholarship in heritage parallels the development of "Heritage Studies" as a distinct area of study within the humanities. Heritage Studies in the late 1980s and early 1990s was in a new field when John Carman graduated in 1989 as one of the earlier graduates of a dedicated Master's-level program in Heritage Studies within the Department of Archaeology at Cambridge University. After completing his Ph.D., he continued at Cambridge as a lecturer until he left for Birmingham University in 2005. Part of a small heritage-focused faculty at Cambridge, he was among the shaping influences in the development of the M.Phil. in Archaeological Heritage and Museums at

Cambridge University from a small program with a few dedicated students to a developed and dedicated cohort of Masters and Ph.D. students which has created a distinct group of heritage scholars in Europe, Africa, United Kingdom, and North America.

Major Accomplishments

During his tenure at Cambridge, the foundation for his current work was laid and his early explorations of the notion of value built on the foundational work by scholars such as Timothy Darville. His focus on value came at a time when many of the definitions and understandings of the notion of "heritage" and the approaches to cultural heritage management first were being explored. His dissertation published in 1996, *Valuing Ancient Things: Archaeology and Law* (Leicester University Press), was the beginning of important work in defining and interrogating how value is created with respect to heritage. Later work exploring cultural property and what he refers to as the "silent discourse" of ownership of heritage (Carman 2005) is a refinement of his earliest research interests and continues to be developed within the context of conflict studies, public interpretation, and in memory studies.

He was an early advocate for the recognition of heritage studies as a distinct field. His 2002 publication *Archaeology and Heritage: An Introduction* (Routledge) was in response to the critical lack at the time of an introductory volume/text for beginning scholars in archaeology, heritage, and museum studies. Moreover, like much of his work, the volume was notable for its interdisciplinary approach to heritage, acknowledging the essential and important relationship between archaeology and heritage, yet also recognizing the distinct qualities of these two means of investigating "the past." The 2009 volume, *Heritage Studies Methods and Approaches* (coedited with Marie Louise Stig Sørensen, Routledge 2009), which arose out of a conference organized by co-organized by John Carman, Marie Louis Sørensen, and their heritage graduate students, typifies his continuing concerns with developing a body of method and theories tailored to and evolving out of research within heritage studies.

A strong proponent of ensuring a continuing dialogue within the field, he has participated in and convened conferences, symposia, and research groups at the local, national, and international levels. Many of these are centered upon the exploration of historic battlefields as objects of heritage. Anchored by his interrogation of how heritage value arises and is assigned – and lately the ideas of ownership and property – he has pursued his wide-ranging research interests in historic battlefields, memory, public archaeology, and the notion of "the public" and museums in international contexts.

Cartajena, Isabel

Victoria Castro
Universidad de Chile, Universidad Alberto Hurtado, Santiago, Chile

Basic Biographical Information

Isabel Cartajena was born in Santiago de Chile in 1965. With a Chilean father and a German mother, she grew up in traditional environment together with his youngest brother. During her youth, she spent short stages in Germany where she could learn about both worlds. Her first link with Archaeology was in her teens during a family trip to Eastern Island where she saw an open-air like museum. Fascinated with the landscape as well as the culture later she would spend several summer periods in the Island.

She firstly was enrolled in Oceanography – claiming that Chile's future was linked to the ocean, however during 1986 she was accepted in the Archaeology program at the University of Chile. As part of the student curricula, she made her practical fieldwork at the Atacama Dessert. Since then, most of her professional career has been linked to the desert.

Today, Isabel is an Assistant Professor at University of Chile, where she has been a faculty member of the Department of Anthropology since 1995. She has been involved in the Zooarchaeological research line in the Department during the last decade, which includes several courses as well as supervising thesis and practical lectures.

Since 1993, Isabel has been engaged in many multidisciplinary research projects together with Lautaro Núñez and Martin Grosjean. With the support of several competitive-based public funded grants, they have developed a long-term research area linking archaeology, geoarchaeology, and zooarchaeology in studying human occupation and paleoenvironments in the western slope of the Atacama Desert. She has participated bringing along her knowledge and experience in the study of animal bone remains that became a relevant indicator about human activities in this area. As a result of this collaboration, the group has published several book chapters and papers worldwide (Núñez et al. 2002, 2005, 2010, Grosjean et al. 2003, 2005).

Recently, she has been fascinated by underwater archaeology. The study of extinct animal remains in a drowned terrestrial site in the Central Chile Pacific coast opens a new research agenda for her.

Above all, Isabel manages to combine her academic and teaching activities with her family duties.

Major Accomplishments

Since her undergraduate studies, she has been working on South American camelids in the Loa Basin and Salar de Atacama region, northern Chile. With the support of national grants as well as from the National Geography Society, she contributed to a multidisciplinary team in several dimensions, especially in the analysis of animal bones and problems addressed to the camelids domestication in the Southern Andes.

With this background, Isabel was enrolled in the Doctoral Program at Freie Universität Berlin and obtained a DAAD scholarship granted by the German government. As part of her doctoral study, she spent 2 years in München at the Institut für Paleoanatomie, Domestikationsforschung und Geschichte der Tiermedizin from the Ludwig Maximilians Universität where she closely worked with Prof. Dr. A. von den Driesch, a world known specialist in Archaeozoology.

Back in Chile, Isabel returned to University of Chile. She is a dedicated teacher and has been recognized among the best scholars of the Archaeology program at University of Chile. She still works in Quebrada Tulán, at the south of the Atacama Basin (Núñez et al. 2006a, b), and is currently researching Early Holocene sites located in the Salar de Imilac and Punta Negra further south.

During 2012, she was the head of the organizing committee of the Second Latin-American Meeting of Zooarchaeology (II ELAZ) held at the University of Chile in Santiago.

Carter, Howard

Dario J. M. Cavallo
Department of Historical Studies, University of Turin, School of Humanities, Turin, Italy

Basic Biographical Information

Howard Carter was a British archaeologist and Egyptologist. He came from a noble family who lived in London, in the district of Kensington. He was born on the 9th of May 1874, his father Samuel John Carter (1835–1892) was a very talented painter and illustrator, and his mother was Martha Joyce Sands (1837–1920).

He spent his childhood in his parents' hometown, Swaffham in Norfolk. Over there he learnt to paint with watercolors, but he never became as talented as his father. Close to his home stood Didlington Hall, the large property of the Amherst's, this family proudly owned a large

collection of Egyptian antiquities. Thanks to this collection, Carter developed a passion toward Egyptian antiquities, and the friendship with the Amherst's led him to join his first expedition to Egypt.

In 1891, a 17-year-old Carter was recommended by the baroness Mary Cecil to Percy Newberry, a friend of the Amherst's, to depict burial paintings and artifacts in watercolors. The fundings for this expedition came from the Egypt Exploration Society (founded in 1882 under the name of Egypt Exploration Fund); the explorations lasted from 1890 to 1894. Once reached Cairo, Carter met Sir William Matthew Flinders Petrie, who recognized his talent and accepted him as a member of the expedition. Carter participated to the excavations of some important sites such as Beni Hasan, Hatnub, and Tell el-Amarna. Thanks to Flinders Petrie, Carter learnt the necessary techniques and procedures to conduct an accurate archaeological study.

From 1894 to 1899, Carter worked on the site of Deir el-Bahari, under the guide of the Swiss archaeologist Henri Édouard Naville. During this expedition, he studied the walls' bas-reliefs of Hatshepsut temple.

In 1899, when Carter was only 25 years old, he was nominated Chief Inspector of the Egyptian Antiquities Service, and he conducted important excavations in the Upper Egypt sites; among the others we can recall Karnak, Luxor, Thebes, Abu Simbel, and Aswan. The tombs of Pharaoh Seti I and Queen Nefertari, spouse of Ramesses II, were some of the most well-known sites that he worked on. During those years, Carter gained more and more knowledge, and he designed innovative techniques of excavation; he was also financed by the Supreme Council of Antiquities to conduct his own projects of excavation. As inspector for Upper Egypt, from 1902 to 1904 Carter worked in the name of Theodore M. Davis (1838–1915), who was a private sponsor for the Antiquity Service. Among the important discoveries of this period we can recall the Tomb of Pharaoh Thutmose IV, known as KV43, excavated in 1903 (See Carter, Newberry, Davis, 2001). In 1904, he was transferred to the Inspectorate of Lower Egypt.

In 1905 the so-called Affair of Saqqara had a negative impact on his career. A group of French tourists had an argument with Egyptian guards that turned into a violent fight. France pretended formal apologies from Carter in quality of supervisor but when the Egyptologist took the side of the guards by defending them, he was dismissed from his position and fired. Despite this unfortunate event, Carter decided to stay and to live in Egypt while making a living by selling his watercolors.

A few years later, a lucky coincidence led Carter back to his career as an archaeologist. In 1908, George Herbert, fifth count of Carnarvon, matured a strong passion for Egyptian antiques, and he went to Luxor with a permit to conduct excavations. He soon understood that he needed the help of an expert and asked Gaston Maspero, General Director of Egyptian Antiques, for advice. Maspero had nominated Carter Chief Inspector in 1899, and he didn't lose his admiration for him since, so he recommended him to Carnarvon. This was the beginning of 15 years of fruitful collaboration between Carter and Carnarvon; the latter financed several expeditions among which a relevant excavation in Thebes that brought a large number of pieces to his collection.

Carter's dream became true when during the excavations in the Valley of Kings, he discovered the tombs of two pharaohs of the XVIII dynasty: Akhenaten (Amenhotep IV) and Tutankhamun. The discovery of the tomb of Tutankhamun, known as KV62, in 1922 made both Howard Carter and Carnarvon famous to the world, and it is still considered one of the most sensational archaeological discovery of all times also thanks to the false rumors about the "curse of the pharaohs."

During 1924 Carter toured America to explain the details of his sensational discovery (Fig. 1) and until 1932 he dedicated his time to the study and cataloging of thousands of artifacts founded in Tutankhamun's tomb (Fig. 2); nowadays we can admire those findings at the Museum of Egyptian Antiquities in Cairo. Shortly after Carter stopped working as an archaeologist and became agent and collaborator of collectors and

museums, such as Cleveland Museum of Art and Detroit Institute of Arts.

He went back to his hometown, Kensington, and he died on the 2nd of March 1939 due to a lymphoma when he was 64 years old. He was buried at the Putney Vale Cemetery; on his tombstone there is a commemorative epitaph. The main source for the biographical information about Howard Carter here presented have been the work conducted by the english journalist Harry Victor Frederick Winstone (1926–2010), who collected a conspicuous amount of material related to Carter's life and especially the Tutankhamun's tomb discovery (see Winstone 1991).

Carter, Howard, Fig. 1 Howard Carter at the Library of Congress, Washington, 8 May 1924. National Photo Company Collection

Major Accomplishments

Carter's most important discovery has been, with no doubt, that of the tomb of the Pharaoh Tutankhamun. When Carnarvon and Carter decided to start the excavation in the Valley of Kings, the works had been under the direction of Theodore Davis since 1902. Lord Carnarvon easily obtained the excavation permit in 1914, but because of the First World War, the works could start just in 1917.

After several years of digging, the results were still very poor; just artifacts of minor importance were found. Because of the expenses, Carnarvon was about to declare the expedition concluded in the summer of 1922, but Carter was so sure that he could find the tomb of the pharaoh that Carnarvon extended the works for one more season. The systematic methodology applied by Carter implied

Carter, Howard, Fig. 2 Howard Carter working on the Tutankhamun's sarcophagus. Photo from The New York Times, 1922

to proceed sector by sector and the tomb was finally discovered in the very last section to be explored.

The excavations started again on the 3rd of November 1922; after a couple of days Carter found the entrance to a staircase that led downward, and nobody had walked on those steps since it was closed. Lord Carnarvon, who was in England at that time, was immediately called back to Egypt to see the opening of the tomb. He arrived in Alessandria on the 20th of November and on the 26th the tombstone was finally removed to open the tomb.

Carter didn't know yet that was Tutankhamun's tomb, but he understood that it was a magnificent discovery when he and Carnarvon saw the rich grave goods for the first time. The sarcophagus of Tutankhamun was not immediately opened, it was in fact handled in two stages, a year apart from the other. Unfortunately Lord Carnarvon died on the 5th of April 1923 and he couldn't assist to the opening; he died of sepsis and pneumonia caused by the infection of a mosquito bite that Carnarvon distractedly cut while he was shaving himself. His sudden death gave voice even on newspapers to rumors about the pharaoh's curse.

The discovery of Tutankhamun's tomb had a huge echo even because of those rumors and Carter became quite popular despite the lack of official information at that time; even nowadays many authors are inspired by those stories to write romances and mystery tales about the young pharaoh.

María Victoria Castro Rojas, her full name, began her academic career in 1969 as an archeological assistant in the Universidad de Chile's Anthropology Department. Her outstanding teaching skills developed from a profound vocation for archeology and were greatly enriched by her previous training as a philosophy instructor (1978, Universidad de Chile). Not long after obtaining that first position, she was promoted to instructor with the same Anthropology Department. In 1981 she graduated with a bachelor's degree in philosophy with a minor in prehistory and archaeology from the Universidad de Chile and then in 1982 was granted the professional title of Archaeologist. In 1998 she obtained her master's degree in ethnohistory from the University of Chile, producing a groundbreaking final dissertation on evangelization and Andean religion in the Southern Andes. In 2007, Castro Rojas was appointed professor emeritus at the University of Chile. She is currently a full professor at the Universidad de

Chile and the Universidad Alberto Hurtado in Santiago, Chile, and regularly lectures in other universities in and out of the country.

With more than 40 very active years of influential research and teaching, Castro Rojas has become a highly respected figure in Andean American archeology. Working with both Chilean and international experts (botanists, ecologists, marine biologists, and linguists), she has created and participated in numerous multidisciplinary projects that address emerging questions about the Andean history of Northern Chile's Atacama Desert. Castro Rojas' broad research interests range from early archaic societies to modern local communities. Her studies have focused on the social structures, ideology, and technologies of pre-Columbian and modern indigenous farming societies that have inhabited the Atacama Desert's valleys and oases in particular. She also has participated in the worldwide historical and theoretical discussion on the complex processes that shaped the cultural landscapes during the Inka State's expansion into the Atacama during the AD sixteenth century and its monumental legacy (Castro 2018).

Throughout her career, Professor Victoria Castro has demonstrated a deep concern for transferring knowledge to local communities and the general public and has encouraged community members to become active agents in defining and reconstructing their own ethnic identities and managing their cultural heritage. Both in writing and in person, she has tirelessly promoted Chile's pre-Hispanic past within the Latin American context at times when political, economic, educational, and cultural policies were informed by outdated views of this past. Few archeologists in the region have been as successful in bridging intellectual divides, including those imposed by discipline, geography, and time. We wish to focus precisely on that visionary practice, as it has enabled Castro Rojas to develop a rich approach that has shed new light not merely upon a particular locality or region but on the entire Andean world. In sum, we present an overview of the thematic versatility of her research interests and contributions.

Victoria Castro was one of the first Chilean archeologists to conduct research in what was later termed Andean history, a concept that has now been accepted by social scientific disciplines and the broader academic community (Hidalgo 2004). This approach maintains that the different peoples that first peopled and then inhabited the vast Andean environment shaped a rich, thousand-year-old cultural tradition marked by periods of intense political-religious cohesion and others of less integration (Castro et al. 2016). Victoria's educational background in history, philosophy, anthropology, and archeology and this confluence of approaches, disciplinary perspectives, and theoretical orientations enabled her to develop a uniquely American perspective on cultural processes, making her research a touchstone for the study of the indigenous past and present of the Andean America. In her work she has striven tirelessly to understand the lifeways of present-day communities in that zone – their beliefs and aspirations, their organization and local particularities, and their sense of belonging to the greater Andean world. In her own words:

> *My interest in studying the Andean world emerged for a host of reasons. Perhaps it came first from my long stretch in the field observing and living with the inhabitants of the Andean countryside during my first field assignment in northern Chile. Also influential were my lectures on the work of John Murra, and especially what I learned in our thought-provoking conversations. In that way I gradually began to develop an understanding of how Andean communities conceived of and lived in their world – it was a nonstop learning process that continued through my studies of Atacama highland communities that were originally undertaken to enhance my understanding of the archeological record*. (Castro 2009a:13)

John Murra's contributions were vital for understanding Andean perceptions and thinking. The radical paradigm shift that Murra proposed for the Andean World in the 1970s used new theoretical models to comprehend Andean social and political structures and cultural dynamics. Murra's (1970, 2002) model of sociocultural complementarity also highlighted the need to work with a variety of information sources, such as original colonial documents and ethnographic and archeological studies. This model presented

a powerful new view of the Andean World as a diverse, dynamic, and interconnected sphere with trade networks organized around decentralized sociopolitical centers grounded in harmonious pan-Andean relations. This view was explored, studied in depth, and applied to different regions by a variety of authors, encouraging the production of further knowledge that enriched archeological, ethnohistorical, and anthropological research (Salomon 1985; Platt 2010). Victoria Castro was among the Andean scholars who endorsed Murra's theoretical and methodological perspectives, which was publicly and privately recognized by the author. This created a deep and mutual intellectual relationship and personal friendship.

Victoria spent time with Murra on several occasions and the two carried on a rich correspondence (Castro 2009b). At one time he was invited to Zapallar on the central Chile coast, where she and Murra, along with Carlos Aldunate and Jorge Hidalgo, recorded a series of interviews with the renowned anthropologist that were later published as Nispa Ninchis (Castro et al. 2000) (Fig. 1). Years later, Victoria would attest to the strong support and unwavering commitment Murra gave to her (as well as other female scholars) at various stages of her intellectual and professional career when she wrote:

> *Murra solidified my holistic comprehension of the Andean world, and of history, and gave me the certainty that by combining the separate tactics of anthropology, archaeology, ethnohistory, and ethnography one could increase the enormous complexity of its unique cultural history.* (Lechtman et al. 2009: 77)

Victoria was the first in Chile to systematically employ an ethnoarcheological approach, in which stories and accounts collected from indigenous populations were used to interpret ancient material remains. It was a groundbreaking approach in the 1970s and 1980s, when Victoria and her team began to employ it in their fieldwork in the Norte Grande (Castro et al. 2013):

> *When I began working in the north, I realized that I couldn't divorce anthropology from archeology, as the people inspired me in my study of the past and what we studied of the past could have meaning for the future as well – that was the nexus. So I always engaged in ethnography, which is the study of traditional peoples. We worked with the interdisciplinary approach of ethnoarcheology, which is now in vogue but when we began was looked down upon.* (Castro 2015) (Fig. 2)

One of the first studies she participated undertook from this perspective focused on *chullpas*, towerlike stone structures, each with a portal halfway up the wall and often with an adobe or stone floor and base. These monumental burial towers are scattered around the Altiplano in Bolivia,

Castro Rojas, Victoria, Fig. 1 Launch of the book *Nispa Ninchis. Decimos Diciendo. Conversaciones con John Murra* at the Instituto de Estudios Peruanos (Lima, July 2000). Peru, and Northern Chile. Early ethnohistoric testimonies from the Altiplano indicate that, at the time of contact with the Spanish, Aymara groups were using the towers that we now call *chullpas* as burial chambers for their dead. However, not all structures identified archeologically as *chullpas* are burial chambers; some of them served various other functions (as residences, silos, territorial markers, and offering sites). At the southernmost edge of the region, the function of Likán *chullpas* of Toconce, (Salado River in Northern Chile) dated to AD 850–1210, was addressed by Victoria Castro y Carlos Aldunate combining an ethnographic approach focused on the ritual practices associated with death in Toconce along with archeological and architectonic studies (Aldunate and Castro 1981; Aldunate et al. 1982). The investigators managed to establish significant relations between *chullpa* contexts and present-day chapels and other religious structures (Aldunate et al. 2003, 2016a). They concluded that the *chullpas* of Likan were used as shrines and that, in front of their portals facing the high "guardian" mountains that dominated the landscape, contemporary burning rituals formed part of a rich world of ideas stretching back to ancient times, as the archeological and ethnographic information obtained shows (Castro 2009c) (Fig. 3). The researchers delved deeper into the worship of mountains, using present-day ethnographic information from Toconce and nearby localities, as well as architectural records

Castro Rojas, Victoria, Fig. 3 Victoria as student recording *chullpas* in Likán (1973). (Photo courtesy Carlos Carlos Urrejola)

of the portals and chapel entryways, which faced the principal summits in the surrounding landscape. They found that the natural and the supernatural were an indivisible unit, according to valuable testimonies that revealed a cosmovision in which humans and the natural world were linked by bonds of reciprocity (Aldunate et al.

2016b; Castro and Varela 2016). It has been shown that the ritual structures used by present-day locals throughout the region – such as chapel-cemeteries and ceremonial plazas – are oriented to these same summits. Through oral tradition the local inhabitants express their thanks, fears, and reverence for those guardian deities of the mountains, who provide humans with what they need for life reproduction (Martínez 1976, 2009; Bastien 1985). Her ethnoarcheological approach has been followed by several disciples (Varela 2002; Godoy 2010; Vega and Salazar 2010; Urrutia and Uribe 2015; Uribe et al. 2017).

In addition, Victoria introduced the study of ethnoscience or indigenous science, which entailed the recognition and eventual integration of the ancestral indigenous knowledge of contemporary communities (obtained through oral exchanges, observation of ceremonies, and definition of ethno categories) as a key to understanding the social and political structures, religion, ideologies, art, and technologies of the past. These approaches have relied upon pioneering interdisciplinary research as well as on long-term ethnographic studies, conducted in a cooperative, respectful relationship with traditional practitioners and knowledge holders.

Each society relates to its natural environment in a unique way, developing particular ways of knowing, managing, using, visualizing, and perceiving the natural world that differ from those used in Western science. On the other hand, following the classic subdivisions of the "natural sciences," the discipline of ethnoscience encompasses areas such as ethnobotany – focused on the plant world – and ethnozoology – concentrated on practices and representations inherent to the animal world – among many others:

> *I also began to see that, if I was studying a territory, I had to understand that territory. One of the things that was so important to the herders, for example, were the plants, and so we began doing ethnobotany. It was the same thing with animals, and so we worked with ethnozoology.* (Palma 2015)

Ethnobotany studies relations between human groups and the plant world: how plants are used and taken advantage of in different cultural spaces and times. Ethnozoology studies present and/or ancient relations between human groups and the fauna present in a given region, or a particular taxon of animals.

Indigenous groups have inherited a deep-rooted social tradition that dates back to hunter-gatherer times and is characterized by high altitudinal and longitudinal mobility among different ecosystems. Over time, most societies opted for an agropastoral, agromaritime, or agrolacustrine economy while maintaining hunting and gathering activities. It is not hardly surprising, therefore, that they have a deep understanding and knowledge of environments and resources, which is integrated into a cosmovision rooted in everyday experience (Castro and Romo 2008).

In consecutive studies conducted in Chile's Norte Grande, one of Castro Rojas' aims was to understand the ethno-classifications and uses of plants employed by different communities, in order to explore how different groups conceptualized landscapes (Romo et al. 1999; Villagrán and Castro 2004; Villagrán et al. 1998, 2003). The results produced a long thematic list of all recognized species with their vernacular and scientific names and the uses of these plants (Villagrán and Castro 2004). The names are mainly derived from the Spanish, Quechua, and Aymara languages. Several of the names recorded correspond to generic ethno-categories and to groups of related taxa, whether on the basis of morphological "kinship" or because they grow in a similar way. The local inhabitants recognize ethno-ecological units in which they have integrated the physiognomy of the vegetation, the altitudinal tiers, and the geomorphology into their belief system and their ecosystem management. Plant species are used for different purposes including forage, medicine, rituals, food, building materials, crafts, and others. Among the Andean peoples of northern Chile, the botanical vegetation units and ecological ethno-categories are analogous; indigenous categories also are part of their taxonomy of ecological tiers that defines usage-based landscape units such as "*campo,*" "*cerro,*" and "*chacra*" (countryside, mountainside, and garden, respectively) (Villagrán et al. 1998, 2003).

Because the descendants of the original Andean peoples view food plants in cosmological

terms, they must make offerings to demonstrate their respect and faith. Thus, in highland communities of the upper Salado River valley in northern Chile, the ceremonial calendar of economic activities uses potatoes explicitly as an offering and a food (Castro 2008).

For its part, knowledge of fauna in the Andean world is intimately linked with all levels of the landscape, with animals seen as other members of the environment, perceived in terms of the places they inhabit, the food they consume, and the practical benefits they bring to humans. Furthermore, underlying any "Andean" classification of environmental elements is a cosmological or natural order in which all elements have a "master," whether human, divine, or ancestral (Castro 1986; Castro and Romo 2008; Castro et al. 2014; Castro and Rottmann 2016).

Wildlife is a source of profound, detailed observation, and when they journey to their pasturelands, Andean herders are continuously noticing animal tracks and other signs on the ground and scrutinizing the skies and the horizon in search of the animals and birds that move through it. Animals are distinguished by their many attributes, including the habitat in which they live – whether a ravine, upland meadow, mountain, or pampa. Their morphology is also crucial for their identification; shape and coloring are decisively important, along with the animal's sounds and songs and the shape and location of their tracks and feces. They are also distinguished by their behaviors and habits, such as the time certain animals "come out" (their diurnal or nocturnal habits), the time of year they "arrive" (seasonal), or if they are there year-round, among other habits. Lastly, the relation between animals and humans is also important. Those that provide food or medicine and those that have a role in rituals or *pagos* (offerings) are viewed positively, while those that bite or sting or harm humans or their livelihoods (by preying on livestock or destroying gardens, or by being perceived of as "evil beings") are seen in a negative light (Romo 2001). Using the aforementioned elements, different species are identified by informal comparison, based on the local people's knowledge of Andean fauna (Castro and Romo 2008).

A major distinction is made between domestic and wild animals, the former being those that are owned and taken care of by humans and the latter those that live freely on the land and have no masters. In the remote past, mountain spirits (*mallku*) possessed all of the animals, and then the *mallku* gave some animals – namely, the llama and alpaca – to humans, "on permanent loan" for humans to domesticate. But the *mallku* reserved the right to take back, borrow, or provoke illness or death in the animals if the humans treated them poorly or failed to strictly perform the rites required to ensure their fertility and wellbeing. Thus, in the Andean world, the owners of livestock must perform *vilanchas* (offerings and sacrifices) to the mountain spirits. The *mallku* also have their own herds, but they are comprised of wild animals that only these deities can control (Castro 1986; Castro and Romo 2008). This arrangement helps maintain the unstable balance of forces through offerings between those who "own" the different elements, thereby upholding relations of reciprocity.

In addition to the insights described above, Victoria pioneered the study of topics related to the extirpation of idolatry in Chile's Andean region (Castro 1993, 2009a). She managed to gain access to an unpublished document dated to 1677 and housed in the Archive of Seville, corresponding to a *Probanza de Méritos* (Proof of Meritorious Deeds) penned by the priest Francisco de Otal, an extirpator of idolatry in "Atacama la Baja" (Lower Atacama) (Castro 2009a). It is one of the first documents on record that addresses the extirpation of idolatry in the Atacama region (Northern Chile) and allows to see the violent impact of that process in the localities of Chiuchiu, Caspana, Lasana, and Ayquina in the province of Loa.

One must recall that in the context of the Spanish conquest and the evangelization of the New World, conversion to Christianity and education in the Christian faith were promoted and supported by the Spanish crown. In addition to building churches to celebrate mass and perform religious education, a policy of destroying so-called "pagan" monuments and places of worship was introduced and encouraged in order to

eliminate "pagan idolatry." A strong aversion to "demonology" and witchcraft was instilled by the Spaniards, who equated idol worship with witchcraft and therefore viewed indigenous religious practices – the adoration of *huacas*, idols, and ancestors – as devil worship. Those beliefs resulted in the forced evangelization of local indigenous populations and the violent extirpation of ancient vernacular ideologies.

The 1677 document is an important source of information about the indigenous peoples inhabiting the coast and seaports (Iquique, Puerto Loa, Cobija, and Colupo) and the inland towns and villages of the Atacama (Calama, Chiuchiu, Caspana, Ayquina, and San Pedro de Atacama) during the seventeenth century. Its descriptions of particular circumstances and individuals convey the relations between the local inhabitants, the holders of *encomiendas* (tribute labor grants), and the civil and ecclesiastical colonial authorities in the highlands. Especially significant is the identification of ancient deities of different indigenous communities, descriptions of the rites and ceremonies they practiced, and the burning of their "idols" (Sotar Condi, deity of Atacama; Sutar Quenti, the hummingbird; Quma Quma, idol of Chiuchiu; Socomba, idol of Ayquina; and Sintalasna, idol of Caspana) and offerings (llamas, *cuys*, coca leaves, and the fermented beverage *chicha*, among other items).

Indigenous peoples resisted the extirpation of their religious traditions clandestinely by using zoomorphic icons representing the fertility of the land and by undertaking prayer ceremonies held to obtain good harvests. Victoria conducted an in-depth investigation of the relation between documentary sources and archeological records to analyze the cults of the monkey, the lizard, and the hummingbird Sotar Condi and its relation with water and sowing (Núñez and Castro 2011). She thus opened up a space for theorizing about the configuration of *Sutar/Quenti*, the hummingbird as a principal deity that potentially spanned the Southern Andes during Inca times and perhaps earlier and was reaffirmed under Inca rule. This deity was associated with the West compass point, with mountains and with the place of the dead, and since colonial times it has been characterized as the bird that is "reborn." Ancient indigenous priests invoked this bird when they required a mediator with the gods. It is said that hummingbirds disappear in winter and then return in springtime, referring to a seasonal hibernation during the southern winter (July to September). According to some authors, hummingbirds were considered divine ambassadors in that season when the buds open and the plants begin to germinate in a great show of fertility (Castro 2004).

Victoria strives to record and analyze religious continuities and transformations in the region, comparing the idolatry described in colonial documents with information from oral accounts, ceremonies, and rituals of the ethnographic present – part of a history that has not been written down but has been kept alive and represents an invaluable resource for understanding Andean thought and daily life. Through her analyses, Victoria has developed a novel conception of the way in which present-day Andean religiosity, as practiced by the descendants of the ancient Atacameño people, fuses Christian elements with a vernacular matrix.

This mode of analysis epitomizes Victoria's holistic viewpoint, in which she uses ethnohistory, archeology, philosophy, and linguistics to trace continuities and transformations from prehistoric times to the present, mapping the ways in which the Andean religion was intertwined with processes of evangelization. In 2009, the Sociedad Chilena de Arqueología honored Victoria for her outstanding contributions to archeology in Chile and South America at the launch of her book *De Ídolos a Santos* at the XVIII Congreso Nacional de Arqueología Chilena (National Archaeology Congress of Chile).

Victoria's decades-long, exceedingly fruitful labor has enabled a qualitative leap in our knowledge of the oldest history of different regions in northern Chile, connecting that past with the present-day local communities. And that perspective has enabled archeology to illuminate this history based on interpretations of the material remains of the American peoples, which is of vital importance in places where no written accounts exist. Anthropology, ethnography, and ethnolinguistic shed light upon surviving aspects of vernacular culture in the lives of present-day

Andean populations, weaving the continuing history of the Andes (Castro et al. 2016). Without a doubt, Victoria's work has profoundly shaped the study of Chile's pre-Hispanic history; the periods of contact, conquest, rebellion, and domination; and the emergence of intercultural relations and new indigenous identities. Contemporary understandings of these complex processes have been deeply enriched by Victoria's diligent efforts, both in her own research projects and through her mentorship of many other scholars. In sum, with its fertile and prodigal intelligence, she has managed to develop innovatively the knowledge referred to the history of pre-Hispanic and indigenous peoples and has fought combatively to position these themes and identities in the academic and political cultural field both nationally and internationally. For this lifetime academic achievements, Victoria has received several national and international distinctions. For her lucidity and commitment to public education, she receives the Universidad de Chile Amanda Labarca 2014 Award, given to prominent women that have influenced in the development of the country. Recently she was nominated to be recipient of the Society for American Archaeology Award for Excellence in Latin American and Caribbean Archaeology 2018 for her significant contribution to archeology and to the construction of archeological knowledge in Latin America or the Caribbean.

Cat: Domestication

Jean-Denis Vigne
CNRS, Muséum national d'Histoire naturelle, Paris, France

Basic Species Information

Based on numerous representations of cats in Egyptian art, it has been widely accepted that Egypt was the place where the intensification of the relationship between cats and humans first began. More specifically, several wall paintings dated to the sixteenth century BCE (18th Dynasty, Middle Empire) dedicated to the cat goddess Bastet make clear that hunters of the Nile Valley used cats to threaten wild birds and chase them from reeds (Zeuner 1963). In the tomb of Baket III, a local administrator at Beni Hasan during the 12th Dynasty (c. 1950 BCE), a painting with a cat associated with a human faces a rat suggests that cats were also considered efficient companions for fighting pest rodents (Malek 1993). Additional evidence comes from a tomb in the Abydos cemetery (1980–1801 BCE) that contained 17 complete cat skeletons associated with offering pots.

It is not clear, however, if the cats of the Middle Empire can be considered domestic animals (controlled and biologically modified by the interaction with humans) or if they were only captive wild animals used by people. Juliette Clutton-Brock (1981) suggested that even modern cats are "intermediate between domestic and domesticated," and she excluded it from the "man-made animals" or even from the "exploited captives" and instead created a specific designation of "exploiting captive." Except for the sophisticated breeds which have been selected during the twentieth century, the behavior and morphology of domestic cats are the least modified by domestication. This is especially true for the skeleton and it is nearly impossible to differentiate archaeological bones of wild cats from those of domestic cats, except the brain case for the latter is slightly smaller. This is why Frederich E. Zeuner (1963: 389) wrote that "Domestication [of cat] is (. . .) often more easily established by the archaeological circumstances of a find than by its osteological investigations." This is also why many scholars who investigated the origins of cats in Ancient Egypt agreed on the fact that the process of domestication of cat could have been initiated earlier than the Middle Empire as suggested by High Empire (5th and 6th Dynasties; Malek 1993) hieroglyphs.

In 1984, a cat mandible was found in the Pre-Pottery Neolithic Cypriot village of Khirokitia (c. 6500 BCE) (Davis 1987). Since there was no wild ancestor of cats on the island during the Pleistocene, this find indicated that the Neolithic people intentionally introduced cats to the island more than 4000 years before the earliest evidence of incipient cat domestication in Egypt. Even though this discovery has been followed by additional cat bones in other sites of the same period, it was not clear if cats were transported to Cyprus as wild animals and released in the wild, since there was no archaeological evidence in either Eastern Anatolia or the Levant for an intensification of the relationship between cats and humans prior to their introduction. Though the controversial presence of a cat on the arms of one of the woman statuettes of Hacılar (Turkey, 6th millennium BCE) suggests cats may have been domesticated earlier, the earliest reliable archaeozoological evidence of domestic cats in the Levant that dates to 3300–3000 BCE (Tell Sheikh Hassan, Huruck phase; Vila 1998) is later. However, it still precedes the evidence in Egypt.

The discovery which definitely made clear that cats were domesticated during the Early Neolithic in the Near East came from a Pre-Pottery Neolithic human grave in Cyprus at the site of Shillourokambos dated to 7500–7000 BCE (Vigne et al. 2004). In this grave the skeleton of a young adult human was tightly associated with an eight-month-old cat which was probably sacrified for the burial ceremony then buried without any skinning or disarticulation. Contrary to other animal deposits in the Neolithic human burial that are composed of parts of animals considered to be provisions for the hereafter, the deposit of a complete cat emphasizes the animal as an individual and implies a strong association between a human and a cat. This means the relationship was not "restricted to material benefit of humans, but also involved spiritual links" (Vigne et al. 2004). Of course, the Shillourokambos cat skeleton does not possess any evidence of morphological modification as a result of the domestication process, nor do the bones of several additional cats found in the same village with clear marks of meat consumption.

More recently, cat remains have been found in much earlier deposits in Cyprus dated to 8300–8600 BCE, a date which precedes the earliest domesticated ungulates in the Near East but commensurate with the cultivation of cereals and legumes on the mainland and in Cyprus (Vigne et al. 2011, 2012). The grey mouse, which rapidly infested cereal stocks, was also introduced to Cyprus about this time (Vigne et al. 2011). Based on these observations, it is possible that humans used cats as efficient agents for fighting rodent pests. In this scenario, which possibly occurred independently 5–6 millennia later in Egypt (Malek 1993), the process of cat domestication could be understood as a kind of auto-domestication: early cereal stocks would have attracted mice to the Neolithic villages, which would have in turn attracted cats (and other small carnivores). Humans may then have encouraged cats to settle in villages to control mice, creating a tighter bond which led to domestication (Vigne et al. 2004).

Elsewhere in the world the domestic cat appears much later. They were introduced to Western Europe just before 0 CE and increased in frequency only during the Late Medieval times (Bobis 1991). In China, domestic cats were present during the Han Dynasty (206 BCE–220 CE) but only become popular several centuries later (Pasquet 1993).

Recent population genetic analyses have excluded all other subspecies as potential ancestors of modern domestic cats except the Near-Eastern and North African *F. s. lybica*. This study demonstrated that modern domestic cats "derive from at least five founders from across this region, whose descendents were subsequently transported across the world by human assistance" (Driscoll et al. 2007).

Çatalhöyük Archaeological Site

Shahina Farid
Çatalhöyük Research Project, Institute of Archaeology, University College London, London, UK

Introduction

The 9,000-year-old archaeological site of Çatalhöyük (pronunciation cha-tal-hoo-yuk) is located in central Anatolia, Turkey, 40 km from the modern regional capital of Konya. The site represents two mounds divided by dried-up river channels that today sit in a flat agricultural landscape. The name of Çatalhöyük means "fork mound" which probably refers to the fact that the road from the nearby town of Çumra divides here in multiple directions.

The East Neolithic mound of Çatalhöyük was a settlement inhabited for over 1,400 years between 7,400 and 6,000 BCE cal. Up to 18 stratifications of occupation have been identified as people abandoned old houses, filled them in, and built new ones on top as well as extending outward. Through centuries of this repeated practice, an artificial mound of about 21 m at its highest point was produced from virgin soil, which by the end of the period extended over 13.5 ha (33.5 acres). An estimated population of between 3,000 and 8,000 people is given for any one time (Cessford 2005a).

Today's irregular topography of the mound implies that perhaps a number of discreet districts evolved into mini centers, which through the centuries of occupation developed into one mound. At the end of the occupation on the East mound, or likely overlapping the end, the focus of settlement moved to the West mound attributed to the Late Neolithic and following Chalcolithic period, which continued in use until 5,500 BCE. The West mound is defined as 5.41 ha but continues beyond the fenced limits of the site under the surrounding fields and therefore likely larger in area than currently mapped. It also appears as a low-lying mound in comparison to the East mound but perhaps was a more sprawling settlement. The transition from Neolithic to Chalcolithic appears to have been seamless, continuing from the last activity at the top of the East mound to the West mound. The definition of this later period is based on technological changes distinguished primarily through pottery production. After the Chalcolithic period, both mounds of the site were used intermittently as a burial ground. These burials span the Classical, Late Byzantine, and Early Islamic periods, but there was no major occupation that disturbed the Neolithic or Chalcolithic sequences.

The site is famous for its great size and duration at this early period in history when people started to settle down in permanent settlements and began herding livestock and planting crops. It is also well known for its dense concentration of "art" and symbolism in the form of wall paintings, wall reliefs, sculptures, and installations.

The flat environs of today owe much to the fact that some twenty-five thousand years ago, during the Pleistocene period, the Konya plain was a lake. By the end of this period, about 13,000–11,500 BCE, the lake was drying out, leaving smaller lakes dotted around the landscape, but the Konya plain was still cold, dry, and inhospitable. It was not until Anatolia experienced a rise in humidity in the early Holocene, the period around 10,000 BCE after the Pleistocene or Ice Age, when alluvial fans began to be formed by the increased flow of rivers into many parts of the plain, which led to soil development and vegetation growth (Hodder 2006).

At the time of the earliest occupation at Çatalhöyük, the landscape may be interpreted as

largely treeless grassy steppe on the drier Anatolian plateau, giving way to open oak-grass parkland with some juniper, pistachio/terebinth, and birch on the foothills and to oak-pine-cedar woodland in the better-watered Taurus mountains. Vegetation would have included a patchwork of grassy steppe around marshlands, sedges, and common reeds within the marshy areas, shrubs on the better-drained soils, and trees along the river margins (Asouti 2005).

Within this richly diverse environment, the site was bordered to the south and east by the mountain ranges of Karadağ, Karacadağ, and Hasan Dağ, the latter only visible on clear days.

Excavations and research have clearly shown that the diversity of resources exploited was from a very different landscape as seen today, one that can be best described as a mosaic of different environments and types of vegetation with marshy areas and perhaps small shallow lakes as suggested by some of the bird and fish bones.

The story of Çatalhöyük began beside a river, today only witnessed by a line of trees that grow along the ancient river course. It was here that the Neolithic site was located near a network of pools joined by small channels, in which the water was relatively slow moving. These pools would have provided clean drinking water, although they may well have dried down considerably in the hot summers, and these pools would have supported small fish, freshwater shellfish, waterfowl, and amphibians (Christopher Doherty, personal communication). The proximity of the river also provided other excellent water resources; there were reeds for matting and roofing, and the river may have provided a means of transport for large juniper and oak timbers used in construction. Çatalhöyük's location in the middle of a marsh allowed abundant wild plants, as well as water birds and eggs, to be exploited. Through drier periods, rich alluvial clays, sand, and lake marl clay used as building material could be collected from the settlements edges. It seems quite clear that from here, the people of Çatalhöyük were able to exploit a range of resources, domestic and wild, wet and dry, upland and lowland, and animal and plant (Hodder 2006).

Definition

A survey of the surrounding region (Baird 2002, 2005) suggests that the settlement developed from small local communities, perhaps to centralize resources that led to the development of longer-term and larger-scale social relations. Little is known about the earliest occupation at the site (restricted by the logistics of excavation); it is possible that the first settlers built stand-alone houses which by the mid sequence (where most of the excavation work has been conducted) flourished as an agglomeration of densely packed mudbrick houses.

Each house was constructed with its own set of four walls built side by side against neighboring structures, creating tightly clustered buildings. There were no ground level access points and no streets or alleyways have yet been identified between houses. People moved around at roof level, which may have been at differing heights and traversed by a series of steps and small ladders. Thus, the roof scape may well have been a focus of daily life along with regular activities that took place inside the buildings. Access into the house was by ladder from an opening through the roof located against the south wall.

Between groups of houses were open areas where domestic waste accumulated. It is from these deposits that the wealth of the daily lives of the Neolithic population is learned through their refuse.

The internal configuration of houses displays remarkable conformity across the site. Houses were typically one or two roomed, although more roomed buildings are found, and access between rooms was through small access holes built in the walls. Size, shape, and orientation of the houses, however, varied. Inside, wooden posts set in small pits against the walls were generally positioned symmetrically that supported crossbeams for the roof made of mud plaster and reeds. Through time, the wooden posts were increasingly replaced as clay pillars, at which stage their function is not currently fully understood.

Internal demarcations created zones for different activities indicating a strong sense of social

organization. The smaller of the rooms generally represented the storage area of the house where clay bins were housed and sometimes other food preparation fittings in the form of shallow plaster-lined basins. The larger of the rooms were furnished with shallow platforms made of an earth core that lined much of the walls, which may have been used for sleeping but also other functions. It was the edges of these platforms that formed the kerbs that defined the internal demarcation for designated zones for food preparation and cooking and crafts such as bead making from stone and bone, basketry, and crafting tools such as obsidian knives and blades.

Some houses were also furnished with a bench extending lengthways into the room. A large domed oven was regularly positioned against the south wall, over which the access hole from the roof was located with a ladder and nearby were small circular hearths for a different type of cooking. Other house "furnishing" would include shallow basins and small plinths. Shallow pits near the cooking area were used as storage pits for stocks of obsidian – a volcanic glass worked into cutting tools, or clay balls (baked balls of clay used in heating and cooking as pot boilers). Changes and variations in the layout of the internal features took place during the life of the buildings. New ovens and hearths were built or storage bins and basins were added or removed.

The walls of the house were repeatedly plastered with white clay that was also used to render the house furniture. Different parts of houses were replastered more regularly than others with some areas having been replastered up to 450 times. In some houses, sections of wall plaster were elaborated with paintings, incised decoration, and relief moldings.

The wall paintings and relief sculpture possibly reflect an insight into belief and rituals of the Neolithic people. This "art" is unique, and even today, after the exciting discovery of parallel sites in southeastern Anatolia with elaborate art, the Çatalhöyük material remains the densest concentration of symbolism found so far in the eastern Mediterranean dating from this time. The wall paintings are generally red and/or black on the white background of the plastered walls. The red is ochre based, and black is generally carbon black. All colors identified at Çatalhöyük to date are mineral based. Some of the wall paintings are abstract compositions of geometric designs or composite handprints; others depict hunting scenes with figures and wild animals. One unusual depiction interpreted as a vulture-type bird hovers over a headless figure that may relate in someway to the headless burials and also a depiction with parallels at the site of Göbekli Tepe in SE Turkey (Schmidt 2001).

Çatalhöyük is well known for the dramatic animal symbolism in the relief moldings and the incorporation of animal parts into installations and architecture, such as leopards' and bulls' heads with large protruding horns set into wall niches and rows of bulls horns set along the edge of benches.

One of the most striking characteristics of the Neolithic houses is that the dead were buried below the floors and platforms. Some houses had up to 65 burials as in one house, others as few as 2 or 3, and some with none at all, suggestive of "kinship" houses where most of a kin-group may have been buried.

The majority of the human burials were primary interments in tightly crouched positions, and there is evidence that they were bound by reed rope or matting. Babies were often buried in baskets made of reeds. Many burials were disturbed due to the repeated use of the same burial location; each time a grave was cut, it disturbed the previously buried body, parts of which were moved aside to make room for the recently dead.

Grave goods are not ubiquitous; many burials contain none. Most are ornaments or components of clothing such as beads, pendants, rings, and belt hooks. Occasionally, burials include tools such as bone points and spatulas and obsidian projectile points or shells containing pigment of red from ochre or cinnabar, green from malachite, and blue from azurite. All of these burial goods represent personal items; but not necessarily exclusive to items that were owned by the dead, some may have been "gifted" to the dead from the living, especially those found with babies and infants.

Some skeletons have been found with removed skulls, which can be linked to the skull cult that is

widespread in Anatolia and the Levant in the Pre-pottery Neolithic periods. When found in the excavations, the contextual location of the skulls varies; some are discarded at the end of the use of the building, and some are placed in post pits at the beginning of the house history. One of the more unique finds was that of a plastered and painted plaster skull found in the arms of a skeleton. On close inspection, it was clear that the skull had been repeatedly plastered and painted over time, a clear indication that this particular head was kept and used in a later ritual. At Çatalhöyük, more emphasis seems to be placed on the individual and particular people and their skulls as seen in this example in contrast to other sites such as 'Ain Ghazal in Jordan where plastered human figures are buried under plastered floors of houses and later dug up for the heads that are then found reburied in caches in pits, and similar examples found on Syrian sites such as Tell Aswad in northern Syria. In eastern Turkey at the Neolithic site of Çayönü, the skull cult is represented in the "skull building" in multiples, and the slightly later site of Köşk Höyük in central Anatolia, skulls are found in cashes (Hodder 2006).

In general, the health of the Neolithic population can be determined by different methods. The limb bone length represents body size from which preliminary results suggest that the Çatalhöyük people were slightly smaller on average than other Neolithic groups in Europe and the Near East at about 1.55–1.85 m. The state of dentitions reflects the diet and the other uses to which teeth were put. The teeth were worn rapidly, as would be expected for early agriculturalists in view of the grit added to food by grinding stones. In adults and younger adults, however, there is very little dental decay. This disease became much more common from middle age onward, so in older people, it is common to see very heavily worn and markedly decayed teeth. This pattern suggests that a good deal of carbohydrate was consumed but that it was largely in the form of starches rather than sugars (Simon Hillson, personal communication). Life expectancy was as much as 55 in a few cases, and baby and infant mortality was high.

Research of the human remains through the analysis of their bones, teeth, and isotopic traces, thus far indicates little difference between men and women. They ate both farmed (domesticated) and wild (non-domesticated) plants and animals and worked hard to grow, collect, and hunt their food (Richards and Pearson 2005). Many of the adult skeletons of both sexes have pronounced arthritis. Osteoarthritis results from a high degree of physical activity, which at Çatalhöyük would include climbing up and down ladders, hunting, plant food collection, and raising and tending crops and animals.

Typically, each house was occupied for between 45 and 90 years, after which they were generally emptied of portable items and the floors cleaned. The roof was collapsed in and posts and beams removed. The tops of the walls were dismantled, broken up and crushed, and used to fill the lower portion of the house. Only when the infill had reached the top of the razed walls were the walls for the new house built, mostly directly on top of the walls of the old house. This "infilling" provided a level and firm foundation over which a new house was built. More importantly, the lower half of each building with its internal furnishings was preserved for archaeologists to discover 9,000 years later. The closure and rebuilding was done on a house-by-house basis possibly with several years between each new construction. This means that houses had to be constructed on the exact footprint of the demolished house, as there was no way to expand in either direction because of other extant houses. Therefore, the plan of the settlement stays very much the same through its accumulation. In this way, the settlement grew as a steady development without any serious breaks or disturbances. Despite being a highly organized settlement, there is as yet no evidence of central administration or any large or "different" structures that may have been the foci of a social hierarchy.

Historical Background

The site was first excavated between 1961 and 65 by James Mellaart. It was in 1952 that James

Mellaart first spotted and noted the site of Çatalhöyük from a distance as he was conducting a survey of the Anatolian Plateau mapping archaeological sites of all periods. This was during his time as a visiting scholar at the British Institute of Archaeology at Ankara (Balter 2005). But it was not until 1958 that he and colleagues reached the site and recognized it as of immense importance (Mellaart 1967). Millennia of erosion had scoured clean the outlines of mudbrick houses with plastered internal walls, while scattered artifacts indicated that the site was wholly Neolithic (Todd 1976). At the time, however, Mellaart was conducting excavations at the Chacolithic site of Hacilar, and so it was not until the 1960s that Mellaart began excavations at Çatalhöyük, and the Neolithic site became widely recognized as of unique international significance.

At the time little was known about the Neolithic outside of the Fertile Crescent, where food-producing societies first emerged as herding livestock, planting crops, and building permanent houses. Indeed, it was generally accepted that there was no evidence of the Neolithic in Anatolia due to the cold climate conditions (Hodder 2006). Mellaart's excavations therefore shifted the boundaries of the Neolithic profile westward, which included the identification of crop cultivation and domesticated sheep, goat, and cattle.

Mellaart's excavations came to an abrupt halt in 1965, and it was not until 1993 that Ian Hodder reopened excavations with permission from the Turkish Ministry of Culture and Tourism and under the auspices of the British Institute at Ankara. Also with Mellaart's blessing.

The Turkish authorities granted Ian Hodder a 25-year-long project by which they were investing in Hodder not only long-term commitment to excavation and research but his commitment to develop Çatalhöyük as a heritage site. The Turkish authorities are keen to realize the long-term benefits of regional tourism and overall, to promote Turkeys rich archaeological heritage. Hodder had committed to develop the site as a major tourist attraction with an on-site visitor center, public display of the Neolithic houses, and dissemination of information, all within the boundaries of due care for preservation and conservation issues of the site.

Hodder had progressed through academia to become a lecturer at the University of Cambridge at the time when he initiated the new project in the early 1990s. Today Ian Hodder is Dunlevie Family Professor in the Department of Anthropology at Stanford University from where he directs the project via its head office at the Institute of Archaeology, University College London. The project is a British-led international project with up to 250 team members from across the globe. Today, the project can boast up to 20 different nationalities in a team of up to 170 team members in any one summer campaign. Hodder's vision of the project was to restart excavations within a theoretical approach using modern archaeological methods. By utilizing the latest techniques, the project is able to conduct intensive and detailed studies to enhance the large-scale results that Mellaart had collected. A large array of scientific techniques and analytical tools are put into practice within a robust excavation and sampling framework.

As well as the full-scale modern archaeological excavation and research, Hodders aim has been to address global heritage needs of conservation and public presentation within a site management plan (Site Management Plan 2004). The ultimate aim is to provide the Turkish Ministry of Culture and Tourism with a well-planned heritage site. Since the start of current excavations in 1993, the project has conducted a detailed program of presentation and public engagement as well as local community projects to enhance local awareness of the site, the Neolithic and archaeology in general. Teams have been involved with the conservation and restoration of parts of the excavated areas. These have been covered with custom-built shelters so that visitors can see the Neolithic houses within their neighborhood setting and also within the temporal sequence. The first of a series of planned replica Neolithic houses has been built for visitor entry, and an on-site visitor center provides small temporary exhibits that allow the project to test visitor responses and tailor displays to changing interests and populations. By providing a range of visitor experiences, the full heritage potential of the site can begin to be exploited.

One of the foundations of the project is the team's acknowledgement that it is the combined

skills of different types of archaeological practices and other perspectives that enhance and help to understand the complexities of a site like Çatalhöyük and the understanding of this period in history. All this is reflected in the makeup of the Çatalhöyük Research Project team.

Key Issues/Current Debates

Material Culture

The excavations and research have clearly demonstrated that a diversity of resources was exploited. Through source analysis and environmental reconstructions, much can be learned about procurement activities and distances people covered for these resources.

Obsidian was one of the most important raw materials that was used, a black volcanic glass that by careful crafting is transformed into razor-sharp tools. Each natural source for obsidian is unique, and artifacts found at Çatalhöyük have been sourced to the mountainous region of Cappadocia, to Göllü Dağ-East and Nenezi Dağ, 190 km away from the site in a direct line. Reaching the obsidian source would have taken several days journeying as the route taken would probably have been circuitous in order to have regular access to water supplies. Through the obsidian route, we may address issues of trading with other people on route or at source. Once the obsidian "supplies" were brought back to site, they were placed as caches in shallow storage pits cut through the floor of the houses and accessed when needed (Carter 2011).

The site is also famous for its many representations of the female form modeled from clay or carved from stone as robust representations of fecundity and interpreted as symbols of fertility and matriarchy. Such iconography attracts groups from the Goddess Community from around the world to visit the site as a place of homage. Other clay figurines include small representations of animals and genderless figures. Male symbols are also represented but much less discussed and perhaps fewer in numbers. These appear as seated stone figures and phallic-shaped natural stones. Male symbolism is also present in the form of bull representations in the wall art and installations.

Different styles of cooking and food preparation were indicated by the presence of both ovens and hearths as well as baked clay balls found in large quantities that were used as "potboilers" in cooking (Atalay 2005). Pottery vessels appear not to have been used for cooking until midway through the sequence when a gradual change in technology created a stronger fabric that was then followed by an increase in the use of pottery. In the early sequence, the absence of pottery has defined the beginning of Çatalhöyük as aceramic (Last 2005), but this is based on small area excavations and may simply indicate that pottery was rare. Nonetheless, the change in pottery technology can be traced through the sequence. Other vessels were made of wood and basketry. Food preparation is studied through the assemblage of ground stone artifacts used for grinding and milling and by investigating the contextual relationships between the ground stone and other materials and cooking facilities. The charred botanical remains provide invaluable information on aspects of the human diet as well as of animal feeding and the management of animals. Through bone chemistry – the study of nitrogen and carbon and the study of microscopic wear on the chewing surfaces of teeth from the human skeletal data – it is clear that meat was eaten but also that domesticated plants were a central part of the Çatalhöyük diet. Analysis also centers on wild versus domesticated plants as sources of food, fodder, matting and basketry, building material, and so on; basically, all plant remains that are used in everyday routines in and around the house and the scope and nature of associated activities across the surrounding landscape.

Çatalhöyük has long been known as a center of cattle domestication, but analysis of the animal bones from the recent excavations shows that the cattle are in fact wild. Moreover, the animal bone data is numerically dominated not by cattle, as previously thought, but by sheep and goat. The vast majority of these sheep and goats are domestic, and their meat supplied most of the protein in the diet. The culling pattern, with most animals slaughtered as juveniles or subadults, indicates that they were raised primarily for meat, with wool (these early sheep are unlikely to have been woolly) and dairy products of little

importance. The ratio of sheep to goats among the specimens determined to species is 7:1, making sheep the main herd animal at the site. The only other domestic animal present is dog. But while sheep provide the staple meat source, wild animals, particularly cattle, appear to hold much greater symbolic significance (Russell and Düring 2006).

By studying the minutiae of the Neolithic settlement, house by house, we build up a picture of a household economy through which, when placed into the larger neighborhood context, allows us to explore the wider issues of settlement, economics, and organization. Were individual households self-sufficient in food preparation and craft production or do we see evidence of communal activities? How big were these communal groups and were they based on kinship and lineage? With a noticeable absence of central administrative organization at Çatalhöyük, these questions are central to our research.

The aims of the current international project at Çatalhöyük involve full-scale modern archaeological excavation and conservation and promotion of the site for visitor access.

The main research direction is to place the paintings and symbolism within a full environmental, economic, and social context. Central questions concern the origins of the site and its early development, social and economic organization, and variation within the community, the reasons for the adoption and intensification of agriculture, the social context for temporal trends in the life of the community, trade, and relations with other sites in the region.

Since the 1960s, much has changed in archaeology. It is simply not enough to present what is found by excavation and how people lived in the past. Most questions posed today are why? What led to changes and developments in our past? How does one Neolithic site relate to another? To this end current research is looking at how Çatalhöyük fits into the overall picture of the spread of farming and community lifestyle after the first appearance of agriculture in the Levant at least two thousand years earlier than the dates for the founding of Çatalhöyük. Since the 1960s, many other important Neolithic sites have been excavated in Turkey, and many more are being discovered. These help to fill the chronological sequence as, as it appears, the Neolithic spread from east to west.

The research at Çatalhöyük therefore looks inward and outward and back and forth. To help us understand why this particular location was settled, we are reconstructing the ancient environment around Çatalhöyük, including the climate through pollen analyses. We can reconstruct the nature of the landscape through the carbonized plant remains and piece together from bone remains the animals native to the region. By studying what the Neolithic people were utilizing around them and bringing into their homes, we should be closer to understanding what is was about this location that attracted these people to settle, why they stayed and what brought about the end.

International Perspectives

While today Çatalhöyük is still one of the best known Neolithic sites in Anatolia and the Near East, roughly contemporary with later Pre-Pottery and the following Pottery Neolithic in the Levant, much has changed in our knowledge of the Neolithic in Anatolia today, and in some ways, Çatalhöyük is no longer unique. We know that there are many earlier settled sites in eastern and central Anatolia and in the Levant that compare in size and complexity. We also know that domestication of plants and animals was well underway in these areas thousands of years before Çatalhöyük. There are local sequences, which lead up to and predate Çatalhöyük, such as nearby Boncuklu Höyük and Pinarbaşı (Baird et al. 2011). In southeast Turkey, the earlier sites of Çayönü (Özdoğan and Özdoğan 1998) and Göbekli Tepe (Schmidt 2001) already show substantial agglomeration and elaborate symbolism while in central Anatolia; Aşıklı Höyük (Esin and Harmankaya 1999) has dense packed housing through the millennium prior to Çatalhöyük. There are many other sites contemporary, or partly contemporary with Çatalhöyük that are known in central Anatolia and the adjacent Burdur-Lakes (Duru 1999;

Gérard and Thissen 2002) region, yet Çatalhöyük retains a special significance because of the concentration of aspects of all of these sites in one place.

Future Directions

The aim for future work remains as before: to situate the elaborate symbolic production at the site within its full environmental, economic, and social context. Another direction is to understand the temporal structure of the stratigraphy at the site. Why is it that some columns of houses made up of several rebuilds endure through time and others don't? Could this stability and "ancestry" be linked to success in production?

Another aspect of the research is the role of religion in the emergence of complex societies (Hodder 2010). The premise is that archaeologists can identify religious behavior in the early Middle East and that changes in such behavior were tied to the emergence of large settled agricultural towns. Current research is addressing who the controllers of such societies were and was control of religion linked to social and economic dominance or a collective involvement in ritual and its relationship to a single place.

Cattle: Domestication and Development

J. A. Lenstra
Faculty of Veterinary Medicine, Utrecht University, Utrecht, The Netherlands

Cattle are a major source of milk, meat, hide, and draught power. In addition, they fulfill roles in religious rituals, festivals, and fighting games.

Several species of cattle were domesticated independently. Around 8500 BC, well after the domestication of sheep and goat, taurine cattle (*Bos taurus*) were domesticated in the Fertile Crescent by taming the now extinct aurochs (*Bos primigenius*, Van Vuure 2001; Teasdale and Bradley 2012). This is consistent with the high diversity of mitochondrial DNA (mtDNA) in

Southwest Asia cattle with haplogroups T, T1, T2, T3, and T5. Independent taurine domestications have been postulated to have occurred in East Asia and Africa, but were not consistent with complete mtDNA sequences, which show that the African T1 and East-Asian T4 haplotypes are closely related to mtDNA variants from Southwest Asia (Lenstra et al. 2014).

The ancestral aurochs was recorded to be a large and fierce animal and to prefer a forest habitat within its broad distribution range in Eurasia and North Africa (Van Vuure 2001). As in other bovine species (see below), domestication reduced sexual dimorphism. Cattle further adapted to the habitat of pastoral society by becoming docile, while ~4000 years after domestication, taurine cattle became predominantly short-horned. Domestication of cattle resulted in a decrease in size, which continued until the Middle Ages and was in Europe largely reversed since the Renaissance. The development of a large variety of coat color patterns and morphological phenotypes and milk or beef production traits continues today (Felius 1995; Felius et al. 2014; Buchanan and Lenstra 2015).

Around 6000 BC, zebu (*Bos indicus*) emerged in the Indus Valley by domestication of *Bos primigenius namadicus* (Teasdale and Bradley 2012), but acquired its characteristic hump only after domestication. Further to the east other bovine species were domesticated (Felius 1995). About 2500 BC on the Tibetan plateau, domestic yak (*Bos grunniens*) diverged from the ancestral wild yak (*Bos mutus*, q.v.). In Assam and Myanmar, the semi-feral gayal (*Bos frontalis*) has been derived from the wild gaur (*Bos gaurus*). In Indonesia and Indochina, domestication of banteng (*Bos javanicus*) resulted in Bali cattle. Other domestic banteng populations in Indochina and Indonesia became introgressed by zebu (see below). Yak, gayal, and Bali cattle are adapted to local conditions and did not spread far from their original wild and domestic range. In contrast, both taurine and zebu cattle spread over most continents (Felius et al. 2014).

Taurine cattle now occupy a large variety of habitats, ranging from tropical Africa to the more temperate Mediterranean, Central and Northern Europe, and the cold of northern Siberia. Remains of Neolithic farms revealed that cattle and other livestock migrated into Europe following two routes, along the Mediterranean coasts and along the Danube, respectively, and arrived 3000 years BC at the North Sea coast (Teasdale and Bradley 2012). North Asia may have been populated via the Caucasus or via Europe. From 4000 to 5000 years BC long-horned cattle migrated into Africa and were followed by short-horned taurines (Felius et al. 2014).

MtDNA haplotypes have revealed several introgressions and transcontinental migrations. Various taurine mtDNA haplogroups are found in Southwest Asia, but the T1 and T3 types dominate in Africa and Europe, respectively. European aurochs carried P haplotypes, which also have been found in European domestic cattle at a frequency of ca. 1/1000. A relatively high frequency of T1 in Iberian and South-Italian cattle indicates prehistoric or medieval immigration of cattle from Africa. Because many Central- and South-American cattle were imported from Portugal, Spain, and Africa, T1 is also found frequently in Criollo cattle (Teasdale and Bradley 2012; Lenstra et al. 2014).

From the Indus Valley, zebu moved to the tropical zones of all continents (Teasdale and Bradley 2012; Felius et al. 2014). Going eastward, zebu reached China, Indochina, and Indonesia, which led to crossing with taurine cattle from the north or indigenous Bibos (banteng, gayal) cattle (Payne and Hodges 1997). Banteng mtDNA in Indonesian zebu populations testifies that domestic banteng cows were incorporated in the zebu breeds (Mohamad et al. 2009).

A westward movement from 2000 BC brought zebu to the Southwest-Asian region of taurine domestication and Africa. In the last millennium BC, indicine introgression into African taurine cattle gave rise to the hybrid Sanga cattle. A second wave of zebu immigration in Africa was prompted by the Islamic invasions after 700 AD. At the end of the nineteenth century, a rinderpest epidemic, to which zebu is more resistant than taurine and Sanga cattle, made zebu dominant in Central Africa. The exclusive finding in African zebu breeds of taurine mtDNA demonstrated that all the time zebu expanded via male-mediated introgression. From the nineteenth century, zebu was in the same way introduced in North and South America (Felius et al. 2014).

The industrial revolution in the eighteenth century initiated the development of specialized breeds, which had a profound influence on the exterior, productivity, and genetic constitution of the taurine cattle. Systematic breeding and genetic isolation eventually led to the development of hundreds of specialized breeds. However, crossbreeding has been common, and genetic surveys demonstrated that breeds still contain a large part of the total variety of the species (Felius et al. 2014).

For comparison of breeds, nuclear genetic markers are more informative than mtDNA (Teasdale and Bradley 2012). Y-chromosomal haplotypes as indicators of paternal lineages revealed sharp genetic east-to-west boundaries that divide the taurine cattle in both France and Germany (Edwards et al. 2011). This reflects the contrast of specialized dairy cattle from the northwestern continental lowland dairy with the central-European beef or dual-purpose cattle (Felius 1995; Buchanan and Lenstra 2015), but also coincides with traditional cultural differences between Northern and Southern Europe (Edwards et al. 2011).

As in human genetics, our account of the history of cattle is now being rewritten by analysis of ancient DNA (Lenstra et al. 2014). A whole-genome sequence of a British aurochs specimen indicated gene flow into British domestic cattle (Park et al. 2015).

Çayönü Tepesi: Bioarchaeology

Hitomi Hongo
Graduate University for Advanced Studies, Shonan Village, Hayama, Kanagawa, Japan

Introduction

Çayönü Tepesi is a mound site located on the Ergani Plain, about 40 km northwest of Diyarbakır,

southeastern Turkey. The site is situated near a tributary of the Tigris in the ecologically transitional zone of the Taurus foothills at an elevation of about 830 m. The research at Çayönü was part of the Joint Prehistoric Project of the Oriental Institute of the University of Chicago that included expeditions in Iraq, Iran, and Turkey beginning in 1947. Excavations at Çayönü were initiated by H. Çambel and R. J. Braidwood as the Joint Istanbul-Chicago Universities' Prehistoric Project of Southeast Anatolia and continued from 1964 to 1991 with some intervals (see Braidwood and Braidwood (1982) and Erim-Özdoğan (2011) for summary and current status of research at Çayönü). From 1985 the excavation continued under the direction of M. Özdoğan, and various studies of excavated material are ongoing under the leadership of A. E. Özdoğan. The site covers an area of 2–3 ha, and by the end of the field season in 1991, the total area exposed was 6,000 m^2, making it one of the most extensively excavated Neolithic sites in West Asia. With about 3,000 years of archaeological sequence (c. 10,000–6,500 cal. BCE), the site also provides important material for investigating economic and social development through the Prepottery Neolithic (PPN) into the beginning of Pottery Neolithic (PN). The PPN at Çayönü is divided into six subphases as listed in Table 1. This Prepottery sequence is immediately followed by early PN (Erim-Özdoğan 2011).

Definition

The major research focus of the Çayönü project was "the recovery and interpretation of evidence of the cultural and palaeoenvironmental conditions within which effective food production was achieved in southwestern Asia" (Braidwood et al. 1974). The project included the pioneering use of interdisciplinary studies in archaeology, with staff members from the fields of physical anthropology, botany, and zoology. As the origins of agriculture and animal husbandry were some of the main questions to be investigated, bioarchaeology constituted the core of the research project.

Key Issues/Current Debates/Future Directions/Examples

Zooarchaeology

Faunal remains collected in the 1978 and 1980 seasons were studied and reported by B. Lawrence (Lawrence 1980, 1982). Although the understanding of stratigraphy of the site at the time was still preliminary, Lawrence observed a shift from the hunting of large game such as aurochs and red deer to the use of domestic sheep and goats by the "uppermost" levels at the site. As fieldwork progressed, these "uppermost" levels came to be understood to correspond to the final two of the six building subphases of the PPN, namely, the Cell and Large Room subphases. The observed changes in the faunal assemblage that were suggestive of domestication include a smaller average size for the sheep and goats, changes in their body proportions, the existence of hornless sheep, and higher proportions of young animals. Equid bones were studied and published by Meadow (1986), who determined that they were most likely from the wild *Equus hemionus* (onager).

Zooarchaeological studies of materials collected between 1985 and 1991 have been

Çayönü Tepesi: Bioarchaeology, Table 1 Chronology of Prepottery Neolithic at Çayönü Tepesi (Erim-Özdoğan 2011)

Subphase	Abbreviation	Date (uncal. BP)	Period
Round building	r	10,200–9,400	PPNA
Grill building (early)	g	9,400–9,200	PPNA
Grill building (late)	g	9,200–9,100?	Early PPNB
Channeled building	ch	9,100–9,000	Early PPNB
Cobble paved building	cp	9,000–8,600?	Middle PPNB
Cell building	c	8,600–8,300	Late PPNB
Large room building	lr	8,200–8,000?	PPNC, transitional phase between PPN and PN

conducted since 1996 (Hongo and Meadow 1998; Hongo et al. 2004). As the understanding of the stratigraphic sequence became clearer and since large amounts of faunal remains had been added to the collection after the initial study by Lawrence, the major goal of the new study has been to document the change of animal exploitation through time. Especially of interest is the timing of the appearance of domestic forms of ungulates and the process of the development of pastoralism. In addition to identification of body parts and taxa, measurement data as well as data on age, sex, and modification of bones have been recorded in the study. Targeted studies of cattle and red deer remains were carried out as they also were for pigs (see below).

Through the 3,000 years of occupation at Çayönü, decreasing exploitation of wild mammals, probably due to continuous human impact on the environment around the site, was coupled with increasing dependence on domestic animals. Through the beginning of the Early PPNB, animal exploitation at Çayönü was based on intensive hunting of wild boar combined with broad-spectrum exploitation of other wild animals. Pigs are the single most abundantly represented taxon through subphase c, their bones comprising more than 30% of the identified specimens. Cattle, sheep, goats, and a wide range of wild taxa, including red deer, gazelle, roe deer, onager, bear, leopard, red fox, hare, and a few other small mammal species as well as some birds, tortoise, and a few fish were also exploited. The proportions of miscellaneous wild taxa (excluding cattle, sheep, goats, and pigs) began to decrease in the cp subphase, dropping to less than 10% in the lr subphase and early PN. Instead, remains from the animal taxa that were to become domestic at some point in Neolithic – pigs, sheep, goats, and cattle – gradually increase in frequency through time and by the lr subphase comprise close to 90% of the identified bone specimens. The main contributors to this trend were the increasing numbers of sheep and goat represented, especially sheep, which were rather scarce in the PPNA levels where they comprised only 10% of the identified specimens. Several lines of evidence (relative abundance of taxa, body size, kill-off patterns, isotope studies of cattle bones) suggest that domestic sheep and goats, as well as pigs and cattle, start to appear as early as in the ch subphase (or even earlier in the case of pigs, see below) (Hongo et al. 2009). Appearance of domestic forms of cattle, sheep, and goat at the end of Early PPNB or beginning of Middle PPNB corresponds with what is happening at contemporary sites in southeastern Anatolia and northern Syria. It seems, however, that the role of domestic ungulates was as merely an additional subsistence option in a broad-spectrum subsistence strategy that lasted for about 1,000 years after their initial appearance. Increased reliance on domestic animals can be seen in the c subphase, contemporary with the clear shift from a broad-spectrum animal exploitation strategy to a strategy concentrating on sheep and goats that was taking place throughout southeastern Anatolia by the Late PPNB.

An important focus of the recent analysis of faunal remains from Çayönü has been pigs, the remains of which represent the most intensively studied part of the site's bone assemblage. Pig remains are the most abundantly represented fraction of the assemblage until sheep and goat remains became the majority in the final PPN phase (c. 7,000 cal. BCE). Whether there is evidence for pig domestication at Çayönü is of particular interest primarily because southeastern Anatolia has been considered as a likely region for early pig domestication, based on the determination of "cultural control" of those animals in the 10th milllennium cal. BCE at the site of Hallan Çemi located near Batman (Rosenberg et al. 1998). In the beginning years of the Çayönü project, Stampfli (1983, in ms. 1966) had already observed that the ratio of domestic to wild pigs at Çayönü was about one to one. Kuşatman (1991) reviewed the evidence for pig domestication using the material excavated in 1978, 1980, 1981 and 1984 and suggested the possibility of the existence of domestic pigs at Çayönü as early as the Middle PPNB. Kuşatman, however, in her analysis did not study trends through time but grouped into one analytical unit the pig remains from all the aceramic levels. Consequently, any

change there might have been over time in the Çayönü sequence remained unclear. The new study beginning in 1996 revealed diachronic trends in the pig data through the course of the PPN toward features that can be considered characteristic of domestic populations, namely, smaller body size and teeth, younger kill-off, and increasing frequency of dental defects (Linear Enamel Hypoplasia) (Hongo and Meadow 1998; Ervynck et al. 2001). Some smaller individuals comparable in size to domestic pigs are found already in the g subphase, and a shift toward smaller-sized animals is clear in the later c and lr subphases. Length measurements of the pig mandibular third molars show that most specimens from PPN Çayönü fall in the size range for modern wild pigs, but increasing numbers of smaller teeth appear in later subphases. Teeth that fall in the size range of overlap for wild and domestic pigs begin to appear in the c and lr subphases. In the PN period, there is an overall shift toward smaller length measurements, with the appearance of teeth that are smaller than the smallest documented for modern wild pigs in the region. Overall, a gradual intensification of human-pig relationships is suggested rather than a sudden domestication event or an introduction of domestic pigs from elsewhere.

Carbon isotope analysis of fatty acid residues on pottery point to the significant use of pork/pig fats at Çayönü (Evershed et al. 2008). There is scarce evidence of ruminant dairy fats, suggesting that the use of milk was later in southeastern Anatolia than in the northwestern regions.

Shells

A few hundred shells were identified by D. Mayer Bar-Yosef (unpublished report). Both marine shells and freshwater mollusks were found. Some, especially marine shells had been holed and were probably used as ornaments. A *Murex trunculus* has traces of malachite inlay. All of the freshwater mollusks are available from the local river system. Marine shells were brought from the Mediterranean, or possibly from the Red Sea, implying the existence of a long-distance trade network.

Ethnoarchaeobotany

The archaeobotanical data at Çayönü is rather limited, as plant remains were not always collected in every field season. Flotation of soil samples was initiated during 1968 season by R.B. Stewart, but no identifiable botanical remains were obtained. Archaeobotanical studies were carried out by W. van Zeist in 1970 and by R. Stewart in 1972 (Stewart 1976). In the 1985, 1986, 1987 and 1988 seasons, van Zeist and G.J. de Roller studied the plant remains in reference to a newly clarified stratigraphic sequence (van Zeist and de Roller 1994). The results of these studies suggest that the habitat of Çayönü in the Neolithic did not differ greatly from the present. The site was situated in a steppe-forest (or savannah) environment of an ecologically transitional zone. The identification of charred wood remains revealed the area to be an open forest of oak, pistachio, ash, almond, and tamarisk. Overall, archaeobotanical studies showed that the mode of subsistence in the environmentally rich eastern Taurus zone was different from that of the Levant. There is no firm evidence of plant cultivation in the earliest r subphase. Wild lentil and wild vetch were intensively gathered. Although morphologically still wild, einkorn and emmer wheat were probably cultivated as early as the ch subphase. Pulses were more abundant than cereals. Field pea, lentil, and bitter vetch were also cultivated. It has not yet been determined whether grass pea and chickpea remains are of the domestic forms. An important point was made in the study of the material from the 1972 season, which is that domesticated plants apparently appeared earlier than did animal domesticates. Fat-rich nuts such as pistachio and almond were, however, widely gathered and, together with wild lentil and wild vetch, continued to play an important role in subsistence even after the cultivation of einkorn, emmer, and pulses had begun. Linseed was also collected. A textile fragment made of flax wrapped around an antler sickle was found in 1988 from the level of the end of c subphase. Small amounts of wild barley were recovered, but barley was probably neither cultivated nor purposely gathered. The abundance of grinding tools and sickles also suggests that cereals became increasingly important during the c subphase.

Anthropology

Human skeletal remains of a total of about 600 individuals have been found at Çayönü. In the earliest r subphase, pit burials were dug in the open areas or under the floors, and the dead were generally placed in flexed positions on their right side in a north–south alignment. These burials and those of the following g subphase were primary and often accompanied by red ochre, stone artifacts, or sometimes beads. A skull with a trace of trepanation was also found from g subphase. The remains of more than 300 individuals were discovered from the so-called Skull Building, a special public building used mainly for secondary inhumations, which was in continuous use from ch subphase up until the end of cp subphase. Most of the skeletons found in the Skull Building are secondary burials, such as those found in a pit filled mainly with skulls and a crypt containing long bones (Yilmaz 2010). An example of their distinctive mortuary practices can be seen in the rows of skulls arranged carefully to face in different directions and separated from each other by piles of long bones. Primary burials lacking their skulls have also often been found in association with the Skull Building. The Skull Building fell out of use in c subphase, and in this period, primary burials are found under the floors of buildings. Burials are absent in the lr subphase, so that the dead might have been buried outside of the settlement.

General demographic studies of the skeletons, such as age, sex, and fertility, as well as their pathology and modifications before and after death, were carried out by Özbek (1988, 1995). Among the pathological conditions in the adults are cribra orbitalia, porotic hyperostosis, osteoarthritis, ankylosing spondylitis, and also osteomyelitis. About 4% of the permanent teeth had dental caries, which signify the consumption of carbohydrates as dietary staples. Studies of the burial practice and taphonomy of burnt human skeletons found from the Skull Building were also conducted (Le Mort et al. 2001). Some of the human bones bear cut marks, suggesting that some skeletons were defleshed before being placed in the Skull Building. Both animal and human blood have been identified by analysis of blood residues (hemoglobin crystals) (Loy and Wood 1989) recovered from the skeletons in the Skull Building, suggesting that mortuary rituals involving animal sacrifice took place. However, these results are open to debate, especially concerning the identification of the species of origin (Smith and Wilson 1992).

Analyses of stable carbon and nitrogen isotopes of the human remains were also carried out in recent years (Pearson et al. 2010, 2013). Samples for analysis were collected from all subphases of the Prepottery Neolithic. The study focused on whether diet was different between the primary inhumation skeletons buried under the houses and those from the secondary burials in the Skull Building. Animal bones were also analyzed to see if there were any fluctuations in isotope ratios resulting from environmental change. The results showed that both animals and humans had a C3-based terrestrial diet. The nitrogen isotope ratios in human, however, revealed a wide range of variation, which meant that there was differential access to food among the inhabitants. The meat of wild and domestic pigs had contributed significantly as an animal protein source. Individuals buried under houses exhibited lower nitrogen isotope ratios, suggesting that legumes and small games were main parts of their diet. Individuals in the secondary inhumations in the Skull Building had higher nitrogen isotope ratios, implying a higher intake of meat (and perhaps more bovid meat, which has a higher nitrogen isotope ratio) and cereals. Analysis of sexed skeletons from c subphase showed that males had more access to meat in general, or to food with higher nitrogen isotope ratios (bovid meat and cereals), than females. Thus, it is surmised that differential access to food resources was dependent on social rank and sex. In addition, analysis of nitrogen isotopes of infant and juvenile skeletons recovered from the burials under houses in c subphase points to the possibility that weaning at Çayönü was done at a time later than that of other contemporary sites in Central Anatolia. At Çayönü, juveniles were weaned between 2 and 3 and a half years of age, about a year later than at other sites. A demographic study of these same skeletons suggests that infant mortality at around

3–4 years of age is much higher at Çayönü and that this might have been an outcome of their weaning practices.

Çayönü: Agriculture and Domestication

Mehmet Özdoğan
Prehistory Section, Istanbul University, Istanbul, Turkey

Introduction

The Neolithic site of Çayönü is a flat mound, situated at the southern flanks of the East Taurus range in the plain of Ergani, 60 km north of the province center of Diyarbakır in southeastern Turkey. The site is located at an elevation of about 800 m within the catchment area of Tigris River, extending 200 m along a small perennial stream; the exact dimensions of the site are difficult to estimate; as 120 m in from the stream, archaeological deposit dips under the cover of the present level of the plain.

The site was discovered in 1963 during surveys of the Istanbul-Chicago joint project under Halet Çambel and Robert J. Braidwood. Excavations at Çayönü took place firstly under H. Çambel and R. J. Braidwood in 1964, 1968, 1970, 1972, and 1978–1984 (Braidwood and Çambel 1982) and from 1985 to 1991 by Özdoğan and Özdoğan (1990) uncovering an area of over 4000 m^2, being one of the largest exposures of the Pre-Pottery Period in the Near East (Fig. 1).

Key Issues

Even though Çayönü covers almost the entire span of the Neolithic Period from the early Pre-Pottery Neolithic up to the end of the Pottery Neolithic Period, the site owes its reputation to its long sequence of the Pre-Pottery occupation. The Pre-Pottery deposits have been categorized

Çayönü: Agriculture and Domestication, Fig. 1 Çayönü, the eastern exposure from the air

Çayönü: Agriculture and Domestication, Table 1 Pre-Pottery Phases

Pottery Neolithic	PN (c. 7000–6400)
Large Room Building Sub-phase	PPNC (c. 7200–7000 BCE)
Cell Building Sub-phase	PPNB Late (c. 7200–7500 BCE)
Cobble-Paved Building	Early PPNB (c. 7900–7600 BCE)
Channelled Building Sub-phase	Early PPNB (c. 8000–7900 BCE)
Grill Building Sub-phase	PPNA-early PPNB transition (c. 8400–8000 BCE)
Round Building Sub-phase	PPNA (c. 9500–8400 BCE)

into six phases according to the distinct building plan types that characterize evolutionary stages in the architecture of the Neolithic Period, each phase being denominated accordingly by the ground plan type of the buildings. Even though each sub-phase comprises several building layers, the main sequence runs as (Erim-Özdoğan 2012) follows (Table 1):

Çayönü has revealed an uninterrupted cultural sequence covering the formative stages of the Neolithic Period, providing the missing links between various evolutionary stages that have been more extensively documented at other sites. The earliest occupation at Çayönü presents a unique model of a complex sedentary hunter-gatherer community, evidencing in its later stages cultivation of cereals and certain pluses and introduction of domestic animals, finally developing the principle components of a farming village. A significant contribution of Çayönü has been to the history of architectural practices, beginning with round-planned hut-like structures of wattle and daub, developing in time to rectangular buildings with stone foundations. The excellent state of preservation of its architectural remains has made it possible to evince the transformation of simple dwellings to structurally developed houses attaining new functions. Grill Sub-phase phase marks the initial stages of transition to tripartite rectangular plan type with raised living floors and vault-like roofing of light materials such as reeds and/or twigs (Fig. 2). Architectural practices have developed through later stages of the Pre-Pottery occupation, by the Cell Sub-phase becoming two-story flat-roofed buildings with solid stone foundations and walls of mudbrick.

From the Grill Sub-phase on, the settlement presents a pre-planned layout with a special communal building being located at the eastern end of the site. By the Cobble-Paved Sub-phase, special buildings were aligned around a large and well-kept plaza that was adorned with standing stones. The plaza persisted until the end of the Pre-Pottery Period. By the Pottery Neolithic Phase, the orderly layout of the settlement was no longer maintained. Special buildings have strong stone

Çayönü: Agriculture and Domestication, Fig. 2 Çayönü, a Grill building

walls reinforced with buttresses, framing a large rectangular space with benches along the sidewalls. The floors of earlier ones are either paved with flagstones or covered with sand, while the latest one corresponding to the Cell Sub-phase has a pink terrazzo flooring decorated with lines of white stones set into the cement-like flooring of burned limestone. One of the special buildings, the so-called Skull Building, signifies the death cult, as the skeletal remains of over 400 individuals were interred in the building (Fig. 3). The Skull Building has several rebuilding phases; the earlier ones consisted of a large round space, while the later had a large rectangular court and adjoining cell-like crypts. While the earlier building phases housed secondary burials, caches of leftover bones, and articulated skeletal parts, the final phase consisted mainly of skulls and long bones. Most of the Cell Sub-phase buildings have single or multiple burials beneath the floors, some adorned with burial gifts (Le Mort et al. 2000).

The Pre-Pottery Phase has revealed a rich and varied assemblage. There is a relatively high percentage of obsidian among the chipped stone assemblage; the ratio between obsidian and flint is almost equal by the end of the period. Along with conventional tools of its time period, there

Çayönü: Agriculture and Domestication, Fig. 3 Çayönü, the "Skull Building" showing two phases: the (round)

were also long obsidian blades – known as "Çayönü blades" – that sometimes exceeded 20 cm in length, with steep-sided retouch and heavy traces of abrasion on ventral surfaces; these artifacts have become the markers of the PPNB horizon at the site (Caneva et al. 2001). Çayönü has revealed some of the most outstanding specimens of ornamental objects of various rocks and minerals; a workshop specialized in bead manufacturing has been recovered in the Cell Sub-phase, revealing the entire process from blanks to finished products. The recovery of artifacts made of native copper and malachite has been an astounding discovery, because in strong contrast to the conventional view, the use of metal was earlier than pottery. The native copper was heat treated and hammered to shape simple tools such as hooks, pins, and inlays (Özdoğan and Özdoğan 1999).

In the earliest stage, Çayönü was dependent on hunting, fishing, and gathering of plants. Wild boar, wild cattle, deer, sheep, and goat are among the most hunted species, and among plants, pulses and wild lentils were important (van Zeist and de Roller 1994). There is some controversy on the date of the earliest domestic pig at Çayönü; however, they appear as the first domestic species at the site during the Channelled Building Sub-phase followed by sheep, goat, and cattle (Hongo and Meadow 2000). Even though pulses continued as the main component in subsistence, wild emmer (*Triticum dicoccoides*) and einkorn (*Triticum boeoticum*) are also present in the Channelled Buildings Sub-phase (van Zeist and de Roller 1994). During the PPNB stage, fully cultivated emmer wheat, domestic sheep, and goat take over from hunting-gathering.

Celtic Art

Imogen Lymbery
Flinders University, Bedford Park, Adelaide, SA, Australia

Introduction

When looking at Celtic art, we must consider two things: who were the Celts, and how do we define

art? The *Oxford Dictionary* defines art as the expression or application of human creative skill as painting or sculpture, producing works to be appreciated primarily for their beauty or emotional power. While this definition certainly encompasses some aspects of Celtic art, where does it leave the everyday items such as jewelry, weapons, tools, and pottery, which serve a functional purpose but also bear some form of decoration or ornamentation (Harding 2007: 6)?

It was not until the sixteenth and seventeenth centuries AD that the Welsh antiquarian, Edward Lhwyd, made the connection between descriptions and names given to ancient Celts and the surviving languages of Western Europe. While the term "Celt" was never used by the early populations of the British Isles and Ireland to describe themselves, linguistic analysis traces the oldest form of spoken Celtic to present-day Ireland (Megaw and Megaw 2001: 10). Celtic culture was never static; throughout the archaeological record, we can see evidence of constant adaptation, evolution, and development in material, style, and manufacture, as well as geographic location (Megaw and Megaw 2001: 10). This entry discusses the origin of the Celts, the various styles of Celtic art, and their location in the archaeological record.

Definition

By trying to use the modern application of the term "art," we run the risk of misinterpreting the significance of Celtic art to its originators (Koch 2006: 89); instead we must analyze the styles and motifs used to draw ourselves a picture of a culture that has little to no written history. The term "Celtic art" is most commonly used to describe the material culture of the group historically referred to as "The Celts": a dominant culture throughout the Late Bronze Age, into the Iron Age, until they were overrun by the Romans during their expansion in the first century BC (Green 1997: 12). As many pieces considered to be Celtic art were clearly made to serve a practical purpose, I use the term "Celtic art," following the Megaws, to encompass elements of decoration beyond those necessary for functional utility, perhaps with an underlying, communicative purpose (Megaw and Megaw 1994: 29, 2001: 19).

Historical Background

The first written records which make direct reference to the "Celts" as a cultural group come from the fifth century BC, in the writings of the Greek historians Herodotus and Hecataeus. Hecataeus makes mention of a population of Celts residing in the Greek colony of Massalia (Marseilles) as well as in ancient Noricum (Austria). Herodotus, in books II and IV of his fifth-century BC *History*, writes of the Celts, referred to as "*Κελτοί*," peopling the region of Danube and the areas beyond the Pillars of Hercules (Straits of Gibraltar) (Powell 1958: 15; James 1993: 7; Green 1997: 11; Cunliffe 2003: 8; Megaw and Megaw 2005: 7; Harding 2007: 3). Here, I use the term "Celts" to refer to groups of people that shared a common identity through their language and religious beliefs, rather than a specific ethnicity (Moscati et al. 1991: 25; Koch 2006: 89). There are three main sources available when looking for evidence of the ancient Celts: written accounts from classical observers, second- or thirdhand accounts that often refer to the Celts as "barbaric"; Celtic written sources, Irish and Welsh hero tales or codes of law written during the Christian period in the seventh century AD; and the archaeological record which, if we are lucky, provides us with artifacts sans context, leaving us to infer the representativeness of any discoveries. Archaeological evidence of Celtic culture has been dated to around 750BC at the site of *Hallstatt*, a salt mine located in what is now central Austria, and the namesake of the first Celtic art style (Jacobsthal 1944: 154; Green 1997: 15).

Celtic Art Styles

The site of Hallstatt contains 1000 graves, most containing extravagant grave goods, and was first unearthed in upper Austria during the early nineteenth century. The arts of the earlier, Hallstatt, Iron Age (c. 750–500BC) has been called lifeless and boring in comparison with that of the later

styles of Celtic art; however, we can see from the patterns used that the Hallstatt style was very much a blueprint for the basis of Celtic design and form (Finaly 1973: 32), identified by the predominant use of geometric and non-representational designs.

La Tène culture takes its name from its geographic origins, a lakeside settlement on Lake Neuchâtel in western Switzerland. The products of the earliest manifestations of this art were designated by Paul Jacobsthal in his magnum opus *Early Celtic Art* (1944). The stylistic divisions used in this chapter largely follow those established by Jacobsthal. The styles mentioned above were first defined by Paul Jacobsthal, and though others have made attempts to re-categorize these over the years, Jacobsthal's terminology is still the widely accepted method.

It is difficult to locate the exact genesis of this "Early style," but archaeological evidence places it at around 500BC, intersecting with the geometric formality of the earlier Iron Age and contrasting to it with the addition of floral, non-contiguous patterns and curvilinear features (James 1993: 15; Megaw and Megaw 2001b, 2005; Garrow et al. 2009). The use here of "La Tène" as a descriptor for this period of Celtic art is merely a generalization covering a set of burial traditions, both inhumation and cremation, in which individuals are interred in a single grave, usually with personal items, in a cemetery (Cunliffe 2003: 66). In the Early style we also see what is referred to as the "orientalizing" of Celtic art wherein Celtic craftsmen begin to incorporate Greek and Italian motifs with the linear and geometric designs of the Hallstatt style with the occasional use of imported coral and amber.

Anthropomorphic faces are ubiquitous in La Tène art and are often present on finger rings; neck and arm rings; foliage designs of Middle Rhine gold leaf; the bases of flagon handles; belt plaques; sword scabbards and chariot fittings; and safety-pin brooches. Though there are many forms of variation, it is apparent that there are two main prototypes for faces in Celtic art, both largely adapted from Etruscan forms, as seen on contemporary metal work imported into the Celtic world. These are the bearded silen and the clean-shaven face featuring hair with a straight-cut fringe. Another feature of some Celtic heads from this period is the reduction of the face to a series of simplified protuberances in a cartoon-like abstraction, a precursor to the later "Plastic" style. Also commonly occurring throughout this period are zoomorphic figures, often in the form of brooches. The predominant zoomorphic representations are bird's heads but other animals, such as sheep and boar, while mythical creatures, like the Griffon, are also present. The meaning these images carried is almost impossible to determine, although we can assume it went beyond a simple fastening of one's garments (Megaw and Megaw 2001b). Certain characteristics of La Tène art also became fundamental features of the following style: previously known as Waldalgesheim, after a rich early La Tène woman's gown, but now more commonly referred to as the Vegetal style.

Vegetal style begins around 350BC, during a period of cultural expansion, and overlaps with the Early, La Tène, style. This expansion heralded a change in Celtic society; the centralized nature of the western Celtic zone gave way to the growth of rural centers, demonstrable by the wider distribution of grave goods in flat cemeteries rather than the rich barrow burials, and suggests the emergence of an oligarchic warrior society in place of a ruling dynasty (Megaw and Megaw 2001b: 107). Following the cultural shift came a shift in artistic innovation, reflecting the societal restructure.

The type site of this phase is the "princess" grave of Waldalgesheim, near Bonn in the Middle Rhine, from which the style took its original name. This chariot burial was that of a woman, indicated by the presence of jewelry and lack of weaponry or other characteristically male grave goods. The golden torque and arm bands, found among other burial items, have little resemblance to other artistic wares from the Middle Rhine region but do feature similar forms of ambiguous anthropomorphic representation found in the earlier styles of Celtic art, demonstrating the overlap between the different stylistic changes (Green 1997: 26; Megaw and Megaw 2001b: 113). Figure 1 is a close-up of one of the Waldalgesheim arm bands; note the human faces peering out from

Celtic Art, Fig. 1 Waldalgesheim "princess" burial arm band. Rheinisches Landes Museum, Bonn. (Photo: JVS Megaw)

within the tendrils. One of the prominent features of Vegetal style is the ambiguous representations and obvious affinities to stylized classical plant or vine tendrils (Megaw & Megaw 2005: 11). Anthropomorphic and zoomorphic forms move from the foreground to the background, now appearing from behind the more dominant Vegetal themes in a so-called "Cheshire cat" (Jacobsthal 1944: 162) style of ambiguity, a prevalent theme across all variations of Vegetal art. Contrasting to the chieftaincy period, the Vegetal style shows a broad distribution and an extraordinarily rapid spread, including its adaptation to regional forms in the east and west (Megaw and Megaw 2001b).

Sword style, deemed by Jacobsthal to be one part of the third phase of early Celtic art, is a substyle of Waldalgesheim beginning around 250BC. More properly to be regarded as a number of regional variants stretching from France to the Balkans (Megaw and Megaw 2005: 11), during this phase longswords were common, worn slung over the back rather than hung from the hip (Green 1997: 95). Motifs and symbols on the swords, notably pairs of dragon-like creatures, are possibly representative of social status, identity, or battle prowess, perhaps also serving an apotropaic purpose. The ritual significance of the

Celtic Art, Fig. 2 Gold finger ring, Waterton collection, Victoria and Albert Museum, London. (Crown copyright reserved)

sword is demonstrated by its frequent presence in graves and offering places, the scabbards bent or "killed" before deposition, following a pattern of ritual destruction which extends back into the early La Tène period (Megaw and Megaw 2019: 12).

Overlapping with the Sword style around the late third century BC, the "Plastic" three-dimensional style was coined as the "Disney style" by Megaw and Megaw (2005: 11). The term "plastic," as used by Jacobsthal, refers to the three-dimensional aspects of this art. This style contains the largest variety of imagery in the form of ambiguous faces, both animal and human, with the use of curvilinear geometric forms that are similar to a cartoonist's art. A fine example of this anthropomorphic abstraction using plant-derived motif is found on a gold finger ring (Fig. 2), possibly from Sardinia, dated around the first half of the third century BC. The most well-known definition of "Plastic" style comes from Jacobsthal's *Early Celtic Art* where he relates the vagueness of the human and animal depictions to that of Alice in Wonderland's Cheshire cat; now you see it, now you don't (Jacobsthal 1944; Megaw and Megaw 2001a: 211, 212).

A pre-Roman art form that is not classified specifically by any one of the styles mentioned above is that of the Celtic coin: first introduced into Celtic society in the third and fourth centuries BC through interactions with their Greek neighbors. The Greeks used coins as a form of tribute and to pay taxes and to pay mercenaries, a

majority of whom were Celts and are believed to have initiated the presence of coinage in the greater Celtic society (Nash 1987: 16; Megaw and Megaw 2001b: 177). The initial adoption of coinage by the Celts followed along the same line as the Greeks, in terms of form and function; though variations in model and material vary depending on location. As the use of coinage grew throughout the Celtic world, the predilection for non-representational art and abstraction saw alterations and adaptations of the classical designs to suit their new Celtic origins (Jersey 1996:6), or, as Robert D. Van Arsdell so eloquently puts it, "Celtic coins look the way they do because that's exactly the way the Celts wanted them to look" (Van Arsdell 1989: 33). Zoomorphic representation, an ever-present theme throughout Celtic history, is certainly not excluded from the manufacture of Celtic coin. The "Horse-and-rider" combination is one motif seen across many variants of Celtic coinage in a plethora of stylistic representations, shown here (Fig. 3) on a silver coin from Boii, near Bratislava, Czechoslovakia.

Romano-Celtic Art

After surveying five centuries of pre-Roman Celtic art, we must now turn to Celtic art of the Roman and post-Roman era. Having conquered Gaul, the Romans spent another 100 years engaging in battles and skirmishes to secure Germany, in AD 15, and Britain, in AD 43 (Bogucki and Crabtree 2003: 142). The Celts who survived this Roman onslaught were assimilated into the Roman Empire over the following 300 years, their culture completely reorganized by the Roman occupation. This is demonstrated in the presence, or lack thereof, of Celtic material culture, particularly metalwork, having survived from this time (Koch 2006: 98). Of the residual items, enamelling seems to have become a more prevalent form of ornamentation, replacing the Early style preference for amber or coral inlay, and we see an increase in the Roman art of die-stamping as well as a stronger presence of linear motif, as opposed to the curvilinear style favored in earlier Celtic art. Though the Roman presence dominated many aspects of Celtic culture, designs and motifs of Celtic origin persevered in items such as the "dragonesque" brooches. This shows a clear amalgamation of Roman technology, present in the use of colored enamels and Celtic motifs. The curved "S" shape and decoration of the brooches hearken back to the La Tène "dragon pairs" (Megaw and Megaw 2005: 69–75). Another change in Celtic art, engendered by the Roman occupation, was an increase in anthropomorphic representation and the presence of religious Celtic imagery (Rankin 1996: 259). Celtic deities now took on anthropomorphic forms, for example, the Celtic horse goddess, Epona. With little to no representation in Celtic iconography before the Roman period, Epona became so popular throughout Roman-Celtic Europe that her image is found across the Celtic world and beyond; in fact, she was the only Celtic deity to be granted a festival day in the Roman Calendar: the 18th of December (Green 1997: 147, 148). The amalgamation of the swirling, ambiguous, and curvilinear art

Celtic Art, Fig. 3 "Biatec" coin featuring horse-and-rider motif. Magyar Nemzeti Múzeum, Budapest. Matissek [Public domain]

of Celtic culture with the rigid, four-square, naturalistic world of Roman expression provided Celtic art with a new source of inspiration, indeed; in Roman Britain, Celtic craftsmen choose to adapt new techniques and motifs to suit old beliefs and ways of representing the tangible and intangible world (Megaw and Megaw 2005: 243).

Christianity and Celtic Art

Another large-scale event that left its mark on Celtic culture was the emergence of a new, Mediterranean-based religion, Christianity. Evidence suggests this new belief had reached the Roman province of Britannia in the early years of the third century AD, and between AD 400 and 600, the Brythonic kingdoms, now called Scotland, were also converted to Christianity (Koch 2006: 98). Travelling missionaries played a pivotal role in the development of Christian-Celtic art; not only spreading the Christian message from Ireland across the continent of Europe but also spreading Celtic religious practices, returning with foreign artistic styles. These were then adapted and combined into Celtic designs (Green 1997: 156). For the first time in the archaeological record, we begin to see Celtic language, artistry, and religious ideals preserved and recorded in illuminated manuscripts (Allen 1904: 232; Finaly 1973: 105). Almost exclusively associated with the Church, the illuminated manuscripts portray Mediterranean and Germanic elements while maintaining the design and motifs of Celtic art (Koch 2006: 103). The images in these manuscripts were not intended as individual illustrations but rather as an iconographic representation of religious scripture. A single illuminated book could contain over 100 paintings, all intimately connected to specific Gospel writings (Backhouse 1979: 7). One such manuscript, *The Cathach* (or battler) *of Colum Cille*, dating to the early seventh century AD, is an incomplete Christian manuscript that takes its name from being carried as a talisman at the front of the O'Donnell army in AD 1497 (Megaw and Megaw 2005: 250). In the *Cathach* the only form of decoration is the enlarged initial letter of each psalm, which is illuminated. In contrast, the *Book of Kells*, perhaps the most ornate of all the illuminated manuscripts, dating to the year c. AD 800 (Simms 1961: 23; Brown 1980: 7; Bioletti et al. 2009: 1043), features exquisite detail. It exhibits the fundamentally Celtic inclination of reducing natural forms to stylized pattern with the addition of bird, animal, and human forms, which are depicted not just as minor parts of the fully decorated or "carpet" pages but as additions to the text itself (Koch 2006: 105). Evidence of this new artistic trend is present throughout the *Book of Kells*. One such example is the "Chi-Rho" page, 34r (plates X, XI Simms 1961) (Fig. 4), which are decorated with various types of interlace, some rectilinear and some zoomorphic (Megaw and Megaw 2001b: 255) and bearing the Greek letters "X," "P," and "I", an abbreviation of Christ, or *Χρίστος*, used throughout the illuminated manuscripts. This method of abbreviation is seen throughout the *Book of Kells*. Other examples include the letters "IHS" for Jesus and "SPS SCS" representing the *Spiritus Sanctus* (Meehan 2018). The "Chi-Rho" page also

Celtic Art, Fig. 4 "Chi-Rho" page from the Book of Kells, folio 34r. Trinity College, Dublin. Public domain; faithful reproduction of a 1200 year old piece of art

features one of the most popular scenes among the illuminated manuscripts: that of two cats playing with two mice who are nibbling away at what can be presumed to be a representation of the host (Brown 1980: 89; Megaw and Megaw 2001a: 209; Meehan 2018). Creating these manuscripts was a costly exercise; pages were most often made of vellum, usually from a calf or a sheep; inks were created using a variety of animal, vegetable, and mineral components; and gold was applied to the pages either as a fine powder or as sheets of gold leaf (Backhouse 1979: 8). While the illuminated manuscripts provided Celtic craftsmen with a new medium for artistic expression, the presence of Early Celtic motifs throughout these works demonstrates the resurgence of Celtic culture and its ability to inform the growing Christian society (Megaw and Megaw 2001b, 2005).

With the development of Christianity came an artistic shift toward that of monumental stone carving, namely, that of the Celtic cross, which date from the period of Celtic conversion to Christianity to the Norman conquest (Seabourne 1989: 5). Found across Ireland, Scotland, Wales, the Isle of Man, and Cornwall (Koch 2006: 915), the crosses were often placed at significant religious sites, either as decoration or an educational tool, but were occasionally used to signify the holdings of the founder of a community as a place marker for a historical event or as a grave marker (Seabourne 1989: 5; Joyce 1998: 75). Initially pillar stones decorated with only a simple cross and perhaps an inscription (Koch 2006: 105), the form of the Celtic cross evolved into large and free-standing monuments, the most well-known of which are the ringed head and high-cross designs, often carved on all four sides with anthropomorphic iconography, animal and plant motifs, and abstract or geometric designs (Werner 1990: 98; Koch 2006: 915). The Celtic crosses located in Ireland are predominantly Christian, featuring iconography relating to the Old and New Testament, as well as hunting scenes that were perhaps significant to the communities in which they were built. There are two main themes of animal ornament: mythical and fantastic beasts; and interlaced animals, such as lions or snakes, birds, and people, woven together to form complex patterns (Koch 2006: 917). Often carved from fine-grained sandstone, the Celtic cross was mounted on a rectangular or pyramidal base, sometimes stepped, and was either carved from a single stone slab or constructed of separate pieces using a mortise and tenon joint (Allen 1904: 234; Werner 1990: 98; Maier 1997: 147). Muiredach's cross (Fig. 5), located at the monastery of Monasterboice, Ireland, is an excellent example of the craftsmanship and iconography of the Celtic high cross. Detailed carvings feature biblical motifs such as Eve handing Adam the forbidden fruit while standing under the apple tree and Cain slaying Abel. There is a depiction of Christ standing in judgment placed at the top of the cross above a scene depicting the weighing of the souls. This is presided over by the Archangel Michael. The Muiredach cross features a capstone in the form of a house or a reliquary and an inscription at the base, as well as two cats, possibly with mice, an echo of the

Celtic Art, Fig. 5 Muiredach's Cross, Monasterboice, Ireland. (Photo: Adriao [CC BY-SA 4.0 (https://creativecommons.org/licenses/by-sa/4.0)])

imagery used in the "Chi-Rho" page of the *Book of Kells* (Harbison et al. 1978: 62). Though the construction, design, and motifs were particular to the high cross, the message remained the same – power, protection, patronage, and piety (Koch 2006: 915). The Celtic cross was testimony to the power of the Christian faith in post-Roman Celtic culture.

Metalwork continued to be a principal means of artistic expression in Christian times, evidenced by the so-called hanging bowls. These are ornate bowls often made of thin bronze, either beaten or spun into a crescent shape and shouldered at the top, complete with rings from which they were suspended (Megaw and Megaw 2005: 247). Below the shoulder, on the outside surface, the suspension rings are secured by decorative escutcheons. These were often reused on other hanging bowls or sometimes kept individually. Some have been found pierced and in non-funerary contexts which suggests they had some sort of individual value or importance. It has been suggested that the Celtic hanging bowls are variants of a Roman design which were adopted by the Celts for use as lamps, handbasins, fine tableware, and/or religious ornaments (Laing 1987: 23), though the real purpose of these artifacts remains unknown. The context in which they have been found suggests that almost all were quite old at the time of their deposition. The largest preserved hanging bowl comes from the great ship burial found at Sutton Hoo (Fig. 6), near Woodbridge in Suffolk, and features decorative enamelled plaques on the internal and external bases of the bowl (Megaw 2005: 247–248).

Post-Roman art heralded an expansion in societal structure and cultural beliefs in Celtic society and is mirrored in the art dating from this period. The Celts devotion to their culture did not diminish under Roman rule (Shirokova 2015: 206). Rather, the Celtic penchant for adapting and incorporating new artistic styles enabled the art to endure. Making use of Roman techniques and materials allowed Celtic art to grow and evolve to suit its changing environs while maintaining its originality. Contrarily, the conversion to Christianity saw Celtic artistic expression expand yet further by incorporating elements of early Celtic art with those of the Christian faith to produce some of the most awe-inspiring works of the period. Though the motifs and designs retained their Celtic identity, the context in which they were used altered to match the new, Christian beliefs. Given fresh media for expression and a new, Christian-inspired purpose, Celtic art was no longer used to display social status, but instead was used for the decoration of sacred pieces whose function was the glorification of God and the teaching of religious scripture.

Key Issues/Current Debates

The main debate surrounding Celtic art is focused around the question of whether "the Celts" can be regarded as a cultural group. While there are a great many similarities between artistic styles and languages, as well as historical references to "Celts" dating back to classical times, some scholars, such as John Collis (2003), question whether material culture and linguistics are enough to categorize a singular "Celtic culture." This question cannot be answered definitively, and this chapter will not attempt to try. However, it is a subject that requires more research and will surely be debated for years to come.

Currently, tracking the changes in decoration and form between artifacts and connecting this to an item with an absolute date have been used to establish chronology (Garrow et al. 2009: 79), and while Jacobsthal's framework is that which is still most commonly used, it cannot provide definitive results. Unfortunately, for the moment at least, the function and significance of early Celtic art remains as ambiguous as its design.

Central America: Historical Archaeology of Early Colonial Urbanism

William R. Fowler
Department of Anthropology, Vanderbilt University, Nashville, TN, USA

Introduction

Central America as a cultural and geopolitical area comprises the modern nation-states of Guatemala, Belize, Honduras, El Salvador, Nicaragua, Costa Rica, and Panama.

Definition

Historical archaeology in Central America developed as an outgrowth of anthropological archaeology and ethnohistory focused on pre-Columbian indigenous peoples and the investigation of their history and culture based on postconquest historical data (e.g., Fowler 1989). One of the primary topics of research in Central American historical archaeology has been the study of early colonial urbanism.

Historical Background

The development of the field has also benefitted from shared interests with architecture, art history, historical demography, historical geography, and social history focusing on the native peoples of Central America during the conquest and the colonial period. Some key reference works from these allied fields for Central America are cited in Further Reading.

Key Issues

The forces of the modern world, referred to as "haunts" by Orser (1996), crosscut through a number of key issues: power, status, domination, race, ethnicity, gender, identity, hybridity, and resistance. These issues form the "effective scales" (slices of space and time, like a geographer's "level of resolution") in multiscalar, dialectic analysis of archaeological landscapes or material culture (Orser 1996: 184–190). In the present case, these issues came into play as distinct social and biological groups – Spanish conquistadors, indigenous Mexican allies, and conquered local indigenous populations – made efforts to preserve their own history and ways of life as they lived alongside each other and entered into social relations in new communities. Unequal relations of power and status led to dialectical

contradictory relationships such as domination and resistance. Attempts to assert, protect, and maintain identities succeeded partially or failed completely, leading to a hybridity derived from an intersection of biological and sociocultural practices which was, in turn, a product of close proximity and permeable social boundaries between groups. Rather than discuss the haunts and issues individually, one may focus on how they relate and intersect in the nexus of everyday practice as seen through a multiscalar, dialectical analysis (Orser 1996: 184–190) of one major theme of recent research, early Spanish colonial urbanism.

The theme of early Spanish colonial urbanism interrogates the forces of colonialism, Eurocentrism, capitalism, and modernity while contextualizing scales of power, gender, hybridity, and so on. A focus on urbanism stems from the trope of the Spanish colonial grid-plan city: a systematic implantation of Eurocentric spatial concepts and values as a strategic element in colonization throughout the Americas. Examination of this theme shows the dialectic between the big forces (Orser's haunts) and issues such as domination and resistance, identity, race, hybridity, and others.

Early Spanish colonial cities in America played a crucial part in the radical transformation of the landscapes of Spanish America. Conquistadors endeavored to found cities in the New World almost immediately after entering a region – in some cases even before violently subduing local native societies. These towns, with few exceptions, were built on a grid plan for reasons of both practicality and cultural tradition.

Henri Lefebvre (1991: 151), taking a Marxian perspective, points out that the grid-plan town was "an instrument of production: a superstructure [serving] a political means of introducing a social and economic structure in such a way that it may gain a foothold and indeed establish its 'base' in a particular locality." Other scholars emphasize that the grid-plan town represented an ideological statement by conquistadors acting on behalf of the Crown to impose moral, legal, and religious order or *policía* (Kagan 2000: 26–28) on indigenous populations. As the embodiment of policía, the grid-plan city symbolized Hispanic civilization itself and evoked a propagandistic statement concerning the power of the empire that translated into very specific notions of spatial patterning derived from the social structure of the conquest. The symbolism of the siting of the government buildings and church on the central plaza underscored the power of the sword and the cross in imposing the Spanish imperial will locally. Thus, in a very real spatial sense, the conquest emanated outward from the plaza and the grid to the surrounding countryside. "The main point to be noted, therefore, is the production of a social space by political power – that is, by violence in the service of economic goals" (Lefebvre 1991: 151–152).

Caribbean Antecedents

The first Spanish settlement in the New World was La Isabela, built in 1494 in Taino territory, on the north coast of the island of Hispaniola, by members of Cristobal Colón's second voyage to America and abandoned in 1498. La Isabela was a fortified town not built on a grid plan. Santo Domingo in 1502 and 14 other cities quickly followed suit on the island, built by Governor Nicolás de Ovando who had been instructed by the Crown to use town foundations as an instrument of colonization. Ovando is often credited with implementing the grid plan in these new towns, but there is some ambiguity on the point of the form of the grid plan employed. The plan of Santo Domingo, while indeed built on a grid, is not rigid; the streets are straight but not parallel, and the polygonal blocks vary in size. Similarly, the main plaza is polygonal and off-center (Tejeira-Davis 1996: 33). Puerto Real, another of Ovando's towns, was laid out in a regular, rectangular format, aligned to a common orientation, and was probably built on a grid plan.

The first two decades of the sixteenth century witnessed the first wave of Spanish urban expansion on the islands of Hispaniola, Puerto Rico, Jamaica, and Cuba, followed by an extension to the mainland in the Isthmus of Panama in 1502 and to Mexico by 1519. Spanish American urbanism then spread from Panama and Mexico to

Central America beginning in the 1520s. By the end of the sixteenth century, approximately 44 Spanish towns and cities had been founded during the sixteenth century in Central America (Meléndez Chaverri 1977). Roughly half of these failed to survive more than 10 years; they probably had little formal architecture and were probably not laid out on a grid plan.

Panama

The first permanently established Spanish town on the American mainland was in the eastern extreme of the Isthmus of Panama; the *villa* of Santa María la Antigua del Darién was founded in the Darién region on the west side of the Gulf of Urabá in 1510 by Vasco Nuñez de Balboa (Sauer 1966: 174). The initial population consisted of about 200 Spaniards, refugees from a failed earlier expedition, who elected Nuñez de Balboa and Martín Samudio as *alcaldes mayores* (chief magistrates). The founding of the town and the election of municipal officials were an act of resistance since these actions took place without legal authority granted by the Crown, yet these were actions structured by Spanish historical traditions of municipal power.

In 1514 Governor Pedrarias Dávila arrived in Santa María la Antigua del Darién, dispatched by the Crown to take over the government and resolve personal disputes in the colony (Fernández de Oviedo 1959: bk. 29, Chap. 8, p. 232). Pedrarias was armed with a series of formal instructions from the Crown to found Spanish conquest towns. This order effectively marked a change in Spanish overseas strategic policy from discovery to colonization. The founding of towns represented a strategy to establish a Spanish military and political presence so that, within the framework of Castilian law, their founders could legally appropriate indigenous labor and goods and enslave local populations.

We know virtually nothing of the townscape of Santa María la Antigua. Archaeological research conducted since 1956 has shown that the ruins of Santa María are located on the Tanela River near the modern village of Tanela, approximately 10 km inland from the coast of the Gulf of Urabá, in the department of Chocó, Colombia (Arcila Vélez 1986; Alzate Gallego 2006). Excavations of the Tanela site conducted by Graciliano Arcila Vélez (1986) indicate habitation by a mixed Spanish and indigenous population but provide few clues as to the plan of Santa María. The zone of occupation appears in seven discrete clusters on a series of low hills ("lometas") rising above the surrounding lowlands. While each individual cluster may have had its own internal arrangement, a formal grid plan is not suggested by Arcila Vélez's data. The core of the town seems to have been located on Lometa A where Spanish ceramics, bricks, nails, glass, mosaic fragments, and other objects were recovered in test excavations placed in an area of 1.9 ha. In this and excavations on the other lometas, these relatively scant items of Spanish material culture were accompanied by a large number of ceramic fragments of indigenous tradition, figurines, roller stamp seals, lithics, grinding stones, and other artifacts. Stratigraphic counts indicate that Spanish material is minimal early on and increases in frequency in uppermost levels. The increase in upper levels could correspond to the arrival of Pedrarias Dávila and the increase in population in 1514. The co-occurrence of Spanish and indigenous materials in all excavation units throughout the site shows that Spaniards and Indians lived and worked together ("convivencia") in Santa María, but there are no indications of technological or stylistic hybridity in material culture (Arcila Vélez 1986: 168). A more recent archaeological project directed by Alberto Sarcina in 2013 identified two distinct zones of occupation at Santa María, the first corresponding to the Cueva village of Darién in which Fernández de Enciso and Balboa established the first Spanish settlement and the other pertaining to the town founded by Pedrarias in 1514 (Cozzolino et al. 2015).

Pedrarias founded six conquest towns in Panama, but the only ones known and available for study today are Panamá Viejo (1519) and Natá (1522). Eduardo Tejeira-Davis (1996) compared the plans of these two cities and found an irregular and polycentric layout for Panamá, a port city, with the plaza being off-center, the house lots

long and narrow, and the streets skewed. The layout of Panamá appears to be closer to the medieval conception of urbanism than to the novel conquest-period grid-plan city (Tejeira-Davis 1996: 43). On the other hand, Natá, an inland site located 15 km up the Río Chico from the Gulf of Parita, near the populous sixteenth-century chiefdom center of the same name, was laid out on a spacious, orthogonal grid with a central plaza (probably) square lots and four-lot blocks enclosed by parallel streets (Tejeira-Davis 1996: 45). Natá represents the first example of a large-scale, orthogonal, grid-plan city in Spanish America. Tejeira-Davis (1996: 52) suggested that it served as the model for similar plans of later cities built in Central America and Mexico, especially Granada (1524), León (1524), Santiago de los Caballeros, Guatemala (in Almolonga) (1527), San Salvador (1528), and Antequera de Oaxaca (1529).

Nicaragua

Some limited archaeological work has been conducted at León Viejo. Most of this work has been aimed at revealing specific buildings: the *convento* of La Merced, the church of La Merced, the Mercedarian chapter house, the cathedral of Santa María las Gracias, the convento of Santo Domingo, and the Fortress. Argüello Argüello (1969: 136–142) presents a detailed description of the cathedral, its dimensions, and building materials. The site was buried by the eruption of Momotombo volcano in 1610, and it has been difficult to reconstruct its plan, but scholars assume that it was built on a grid plan. The total area of the town is estimated at 40 ha.

Honduras

Six separate and independent conquistador companies operating in Honduras-Higueras from 1524 to 1539 launched *entradas* (armed incursions), struggled against one another for jurisdiction, founded towns, relocated towns, assigned *encomiendas* (formal grants of labor and commodity tribute), and started slaving and mining operations. All of these actions took a heavy toll on the indigenous populations. Not surprisingly, a series of indigenous rebellions also occurred in the regions of Spanish intrusion from 1524 to 1544, especially during the great revolt of 1537–1539 (Chamberlain 1953). With regard to the critical role of urbanism and the deployment of the sword and the cross in the wars of conquest, an especially interesting episode concerns the resiting by Montejo of Gracias a Dios in 1539 from the site originally chosen by Gonzalo de Alvarado in 1536 which was said to be too low, too unhealthful, too weak militarily, and too far from centers of indigenous population for the service that *vecinos* (resident heads of households) of the city required. Montejo appointed his brother, Juan de Montejo, and an ally, Bishop Cristóbal de Pedraza, as co-administrators to transfer the town to the new site (Chamberlain 1953: 108). The plan of the new city was traced, and Pedraza erected a cross at the main plaza. Pedraza described the transfer and the ceremony of the reestablishment of the town which involved the construction of a shrine at the place where the church was to be built, the singing of a hymn, the ringing of bells, and the saying of a mass (Chamberlain 1953: 109).

Guatemala

The first Spanish foothold in Guatemala was established during the first invasion of Guatemala in 1524 at the Kaqchikel city of Iximche (Guillemín 1965; Luján Muñoz 1994). Although it was not much more than a military encampment, it is regarded historically as the first capital of Santiago de los Caballeros. After its location at Iximche, Santiago became a peripatetic capital for 3 years, with sequential locations in Olintepeque and Comalapa. The Hungarian historian Janós de Szécsy identified the first permanent location of Santiago de los Caballeros, occupied from 1527 to 1541, beneath the modern village of San Miguel Escobar, in the valley of Almolonga. This conquest town had about 100–150 Spanish *vecinos* with indigenous slaves and servants. As this was a time of warfare and instability, however, it is doubtful that many of the *vecinos* lived a settled urban existence. It is assumed that the layout was a typical grid plan, but this assumption has not

been confirmed archaeologically. An indigenous town of several hundred resettled Mexican auxiliaries and their families was located in the village of Almolonga or "Ciudad Vieja," about 2 km to the west. Destroyed by an earthquake and lahar (mudflow) in 1541, Santiago was relocated and rebuilt in the valley of Panchoy on the site known today as Antigua, Guatemala, beginning in 1543. Early colonial Antigua is known only through textual descriptions. Most archaeological excavations conducted in Antigua have been salvage operations on the remains of colonial churches and monasteries (under the stewardship of the Consejo Nacional Para La Protección de la Antigua Guatemala [www.cnpag.com]).

El Salvador

The best preserved example of a conquest-period grid-plan town in Central America is Ciudad Vieja, El Salvador, the ruins of the first *villa* of San Salvador, located in a rural area 10 km south of the modern town of Suchitoto (Fig. 1). Dispatched from Santiago in Olintepeque, Guatemala, under the command of Gonzalo de Alvarado, a small group of Spaniards, accompanied by Mexican auxiliaries, founded the first villa of San Salvador in April 1525, probably on the same site as the later 1528 settlement. The first European town of El Salvador was built in the valley of La Bermuda, a small pocket to the north of Cuscatlan Pipil territory that had little or no indigenous settlement at the time of the conquest (Fowler and Earnest 1985), but it was still prone to attack, especially from the west and the south. The Pipils rebelled and drove out the Spaniards sometime in 1526 (Barón Castro 1996: 39–44), forcing them back to their base in Guatemala. Pipil resistance waned by early 1528, however, allowing the Spaniards to return and found a permanent settlement, which resulted in the second founding of the villa of San Salvador on 1 April 1528 by

Central America: Historical Archaeology of Early Colonial Urbanism, Fig. 1 Location of Ciudad Vieja within the modern republic of El Salvador. (Map by Lauren Kohut, Vanderbilt University Spatial Analysis Research Laboratory)

73 conquistadors and their Mexican allies under the command of Diego de Alvarado. All of the Spaniards declared themselves residents of the town; many of the Mexican allies remained as well (Barón Castro 1996: 87–91, 197–202; Fowler 2011). The town was abandoned 15 years later and moved to the modern location of San Salvador in 1545 (Fig. 1).

Archaeological research at Ciudad Vieja conducted from 1996 to 2005 (Fowler 2011) has established that the town was built on a grid plan on a site with no previous occupation covering a core area of 45 ha (Fig. 2), virtually all of which was artificially leveled and filled with various types of constructions making it an urban landscape of truly impressive proportions. Like the urban plan of Natá, described above, the plan of San Salvador is strictly orthogonal, a paragon of the conquest-period Spanish American grid-plan city. Visitors to the city, Spanish and Indian alike, in its prime of occupation and expansion, say about 1535, surely would have been impressed with the strict, orderly layout of the townscape with the spacious plaza at the center, the church to the east of the plaza, the *cabildo* (town hall) and other municipal buildings on the north, stores and shops on the west, and a tavern and blacksmith's shop on the south. Long, straight streets run from (or into) the four corners of the plaza in the cardinal directions. The one exception to the straightness of the streets is the street running south from the church (and the southeast corner of the plaza) which curves around a natural spring, probably an important water source during the period of the town's occupation. Other streets run parallel and perpendicular to the main streets, bisecting each other to form large lots, most of which were probably subdivided into quadrants for the purpose of assigning them to residents. The plaza measures approximately 100 m on a side including the spaces around the interior streets along the edges of all four sides. The square city blocks measure approximately 80 m (roughly 100 Spanish *varas*) (1 vara = 83.5 cm) on a side, bounded by streets about 8 m in width. Most of the blocks were probably subdivided into four *solares* or house lots of approximately 40 × 40 m (50 × 50 varas) as shown on the projected grid in Fig. 2.

The town displays a great deal of internal functional variability. Among the 18 structures and activity areas that have been excavated, Spanish and indigenous or mestizo residences, ritual spaces, civic/administrative buildings, food preparation areas, commercial and industrial buildings, warehouses and storage areas, terraces, ramps, and defensive features have all been identified. The latter consist of guardhouses, sentry stations, and a steep defensible cliff sloping away from the south and east sides of the site. While the overall town plan shows strong adherence to the grid-plan layout, excavations and remote sensing data show that there was no prevailing norm governing the locations of structures within solares or the size, shape, and internal arrangement of rooms within structures. There is even significant variation in orientation of structures or units of structures. Spanish buildings are distinguished by multiroom floor plans, substantial stone foundations measuring 83–84 cm (1 *vara*) in width, brick tile floors, ceramic roof tiles, and the use of iron nails and other hardware to secure structural elements. They are generally oriented to the overall site alignment of 12°, but exceptions do occur. Buildings assumed to be indigenous or mestizo related tend to be one-room structures with narrow foundations, packed earth floors, and no evidence for roof tiles (indicating thatched roofs). Their orientation does not follow the overall site grid. Thus, while the overall urban layout appears quite rigid at first glance, there is actually a great deal of flexibility and variability in internal distribution and use of space.

While Spanish presence is clearly indicated by the townscape, the architecture, and certain industries and classes of material culture such as iron, brick, and glass, we also see a strong indigenous presence at San Salvador reflected in the material culture of Ciudad Vieja. Indigenous residents of the town would have included indigenous Pipils as well as Mexican (Nahua and Mixtec) and Kaqchikel groups allied with the Spaniards during the conquest. Excavations and surface collection recovered more than 60,000 sherds, and project ceramicist Jeb Card (2007) analyzed more than 10,000 sherds. Aside from a very small number of

Central America: Historical Archaeology of Early Colonial Urbanism, Fig. 2 Plan of Ciudad Vieja, El Salvador, showing natural topographic and cultural features. (Map by Conard Hamilton, Ciudad Vieja Archaeological Project)

Spanish imports, the ceramic complex is eminently indigenous displaying many forms and decorative modes representing continuities with Late Postclassic materials as well as hybrid forms and motifs developed during the conquest period. In addition to the highly visible concentrations of ceramics, obsidian artifacts occur in great numbers on the surface and were recovered in excavations in all excavated loci. *Manos* and *metates* (grinding stones) for maize processing occur in domestic contexts and on the surface. Ceramic spindle whorls for spinning thread, found in association with indigenous residences, suggest gendered production practices. Polished ceramic ear flares and jade objects – elite bodily adornment – are significant in the inventory of indigenous-associated items and maintenance of indigenous identity. In sum, the archaeological evidence indicates that this Spanish American town had a native Mesoamerican population of significant proportion and that at least some members of this population were engaged in maintenance or construction of indigenous identity. Nevertheless, others entered into relationships and engaged in activities that led to hybridization.

Jeb Card (2007) analyzed the ceramics from eight excavated contexts and structures at Ciudad Vieja and from an extensive surface collection of the site. The most striking aspect of the collection is a class of serving plates produced with native Mesoamerican techniques and painted designs but with forms copied from European majolica. Card refers to these vessels as "hybrid plates." Card seriated the forms of published European majolica plates and found that the hybrid plates of Ciudad Vieja could be dated very precisely with this method. Application of this method confirmed the historically documented occupation span of the site (1525/1528–1545), with a slightly later abandonment than documentary sources indicate, possibly to as late as around 1560. The heavy use of hybrid plates in Spanish and indigenous or mestizo households invites comparisons with other cases of forced indigenous displacement in early colonial Spanish America (Card 2007: 276–299). Analysis of vessel form and function from eight excavated contexts of Ciudad Vieja shows similar activities in Spanish and indigenous households, as well as the identification of a tavern or other commercial food and beverage vendor in the center of town. Three microstyles crosscut other classificatory categories suggesting localized or household distribution and likely local production of ceramics in the town. These microstyles disappear during the later years of the occupation of the villa of San Salvador, and Card suggested that this development indicates the formation of new community cultural practices that tended to swamp the initial microstyle variability. Card used these analyses to evaluate models of colonial societies, suggesting that a model of creolization and ethnogenesis would be useful for understanding other interactions in early colonial Mesoamerica.

Subsistence production taking place in or near the town would have included local cultivation, hunting, and fishing – male activities – but the majority of food consumed in the town probably was obtained from tribute rendered by conquered Pipil and Lenca towns in the surrounding region and the hinterlands. Tribute payments to San Salvador are enumerated in the 1532 *Relación Marroquín* (Fowler 1989: 25–26, 155–186). This extraordinary document from the Archivo General de Indias in Seville (Audiencia de Guatemala, legajo 52) contains rich economic and demographic data on approximately 90 indigenous settlements that had been assigned in *encomienda* to the Spanish *vecinos* of San Salvador. The document shows that maize, beans, chili peppers, turkeys, venison, salt, dried fish, honey, beeswax, firewood, and a variety of woven cotton cloth and clothing were paid in tribute by Pipil- and Lenca-conquered communities. Tribute was delivered to San Salvador by male porters from the communities. Failure to pay tribute was met by violent force.

Encomienda labor was virtual slavery, and labor tribute was rendered by almost all Pipil communities, taking the form of male agricultural, construction, mining, or trade labor (in addition to burden bearing) and female domestic service such as cooking, cleaning, and child-rearing. Many if not most Spanish households would have had numerous servants from *encomienda* communities as well as indigenous slaves obtained as war

captives or through barter. During the great Indian revolt of 1537–1539, Governor Francisco de Montejo of Honduras appealed to the *vecinos* of San Salvador for support and war materiel. They responded by sending a Spanish captain with 100 native auxiliaries and 1000 indigenous (probably Pipil) porters carrying gunpowder, harquebuses and balls, crossbows and bolts, swords, lances, shields, armor, and iron bars from which to manufacture points for crossbow bolts. They also sent livestock. The porters delivered their loads to Honduras and remained for an unstated period to serve the Spaniards at their destination (Chamberlain 1953: 87).

A significant but poorly known aspect of the economy of San Salvador, and early colonial Central American cities in general, was slaving and slave trafficking. Until the passage of the New Laws in 1542, the enslavement of indigenous people was legal as long as their captors claimed that the natives resisted colonial domination. Even after the enactment of the laws, slaving was still rampant until the implementation of the laws with the arrival of Alonso López de Cerrato from Santo Domingo in 1548 as president of the new *audiencia* in Gracias a Dios (Sherman 1979: 132–136). Slaving operations began in Guatemala and Cuscatlan during the first Spanish invasion led by Pedro de Alvarado in 1525 (Sherman 1979: 27). Alvarado himself is credited with being the largest slaver in Guatemala and one of the largest slaveholders in Central America, but Diego de Holguín, the first *alcalde* of San Salvador in 1525, claimed that his 50 slaves had been taken away from him when the New Laws were enforced in 1548 liberating the slaves (Sherman 1979: 71). The construction and maintenance of San Salvador would not have been feasible without a large slave labor force. Wealthy *vecinos* of Santiago and San Salvador had trained gangs of slaves working in gold and silver extraction operations in Honduras. During Alvarado's time in Honduras-Higueras, there were 20 or more of these gangs each with an average number of slaves of 15–25 (Chamberlain 1953: 112). Slaving was the most important economic activity in Nicaragua in the 1530s; slaves taken in Nicaragua were shipped to Panama and Peru. Spanish *encomenderos* of San Salvador participated in the same activity, although on a relatively smaller scale, taking slaves in the eastern Lenca territory of Chaparrastique or Popocatepetl, until slaving was curtailed by native population collapse in the 1540s and the implementation of the New Laws in 1548 (Barón Castro 1996: 136, 166–167). Cerrato liberated 500 Indian slaves from about 40 *vecinos* of San Salvador in 1548 (Sherman 1979: 148).

International Perspectives

The people and politicians of the Central American republics regard early Spanish colonial towns as the places of origin of their national identities. Yet, Central American conquest towns are few in number, and even for those that are reasonably well known and accessible, such as Ciudad Vieja in El Salvador, León Viejo, Nicaragua, and Panamá Viejo, research and cultural heritage management has been underfunded. These sites, with the possible exception of Panamá Viejo (Arroyo 2010), remain underdeveloped as places of educational tourism.

Historically, the Spanish perspective has tended to regard these towns as sui generis accomplishments of Spanish civilization, seldom taking into account that in many cases the majority population of the towns was indigenous. Interpretations have emphasized the rapid spread of the grid-plan layout in the Caribbean and on the American mainland and the accompanying implantation of structural (institutional) frameworks. This perspective is beginning to change as Spanish scholarship on early Spanish American conquest towns adopts a practice-based rather than an institutional-based approach in research.

In 2012 an international organization, the Red Iberoamericana de Investigación del Urbanismo Colonial (RIIUC – Iberoamerican Network for Research on Colonial Urbanism), was founded by a group of scholars based in Spain, Argentina, and Peru (Vela Cossío 2014). The core group soon expanded to include specialists from El Salvador, Panama, and the United States. Since 2012 the network has sponsored five international, multidisciplinary seminars which brought together

archaeologists, architects, architectural historians, geographers, historians, museologists, conservators, and cultural heritage specialists from Spain, Portugal, France, Argentina, Brazil, Chile, Costa Rica, El Salvador, Guatemala, Mexico, Nicaragua, Panama, and Peru. The proceedings of four of these conferences have been published recently (Calvo and Cocco 2016; Fowler and Escalante Arce 2017; Vargas Pacheco 2016; Vela Cossío and García Hermida 2014), and the volume for the fifth meeting is in press. The wide range of topics and spatial coverage of these volumes demonstrate the robust character of current research on early Iberoamerican colonial urbanism.

Future Directions

Future research at early Spanish American colonial urban sites will profit from research designs that combine meticulous fieldwork methodologies with dialectical, multiscalar analysis. The discussion here is less a rigorous application of multiscalar analysis than a demonstration that such analysis is feasible and productive.

A promising direction for future research could be the development of a focus on archaeological studies on the scale of resistance and perhaps even studies of overt rebellion rather than everyday resistance to Spanish political and cultural domination in sixteenth-century indigenous settlements, contemporaneous with Spanish conquest towns. The realization of this goal will involve stepping outside the grid plan and devising research on rebellious communities in the surrounding catchment regions. Another underdeveloped scale of analysis in Central American historical archaeology has been sexuality and intimacy. A trendsetting example may be found in the recent research of Russell N. Sheptak et al. (2011, 2012) on the pre-Hispanic and colonial town of Ticamaya, Honduras, an important settlement in native military and political strategies of resistance in the early sixteenth century. These authors present an intriguing practice-theory approach to Ticamaya dealing with sexuality mediating race, class, and warrior status and the transcendence from this scale to that of resistance to colonial domination.

Central and West African Middle Stone Age: Geography and Culture

Nicholas Taylor
University of Western Australia, Perth, WA, Australia

State of Knowledge and Current Debates

Introduction

The Middle Stone Age (MSA) of sub-Saharan Africa is defined by the appearance in the archaeological record of stone tools struck from carefully prepared Levallois cores. Currently dated to around 300,000 years ago, this innovation in toolmaking is associated with the rapid emergence of distinctive regional artifact styles and the effective abandonment of the large handheld hand axes and cleavers that were the hallmark of preceding Acheulean lithic industries (Clark 1988). This technological change reflects a fundamental shift from the use of handheld tools to the attachment (hafting) of stone implements to organic handles for use. In the last three decades, knowledge of this transition and of the MSA cultures that followed has taken center stage in the study of human evolution (Barham and Mitchell 2008). New scientific dating techniques accurate beyond the 40,000 year limit of the radiocarbon method have revealed the time span of the MSA to be approximately 300 to 45 thousand years ago, a period now known from genetics and the fossil record to encompass the anatomical evolution of our species, *Homo sapiens*, in Africa. Archaeologists have thus focused on the African MSA as the probable source of the distinctively modern behavior and cognition (thought processes) that makes us human.

The question of exactly when, where, and how the brains of MSA hominins (humanlike ancestors) evolved into recognizably human minds has led researchers to focus on a range of key archaeological indicators that are generally considered to reflect "modern" behavior and cognition. In addition to the use of hafted technologies and artifacts made of organic materials, these behavioral markers include (but are not limited to) the manufacture of blade and deliberately blunted ("backed") blade stone tools; the dedicated and cooperative hunting of large, dangerous animals; dispersal into new, challenging environments (e.g., forests, highlands, deserts); extended mobility and intensive, seasonal resource exploitation; and symbolic activities including self-adornment, image representation, and burial (McBrearty and Brooks 2000). Paleoanthropologists continue to debate whether these behaviors emerged gradually among archaic *Homo sapiens*/*Homo heidelbergensis* populations before the anatomical evolution of *Homo sapiens* 200,000 years ago or appeared only later, after *Homo sapiens*' anatomy. Interpretations of the archaeological record and of the criteria used to identify "modernity" remain contentious; however, it is increasingly clear that the cognitive and behavioral adaptations that evolved in the African Middle Stone Age played a critical role in the subsequent global dispersal of our species out of Africa sometime after 100,000 years ago.

Knowledge of the MSA and its potential evolutionary significance has not developed evenly across all geographical regions of the African continent. Current understanding has primarily been advanced through archaeological fieldwork exploring long, datable sites and sequences found in Southern and East Africa and North and Saharan Africa. Far from leading this debate, the Middle Stone Age in Central and West Africa remains critically understudied and very poorly understood, a fact perhaps made more surprising when the scale of these two regions is considered. As defined by modern political boundaries, Central and West Africa exceed 6.1 and 2.6 million km^2 respectively, and in combination cover some 28% of the African landmass. The location and geographical size of these regions is shown in Fig. 1, along with the key archaeological sites referred to in this entry. The legacy of colonialism means that both regions today include French- and English-speaking nations and peoples. Central Africa stretches from the volcanic highlands and vast lakes of the Rift Valley in the East to the Atlantic Ocean Coast in the West and from the Okavango

Delta and Zambezi Rivers in the South to Lake Chad in the North, where it borders West Africa. Geographically, Central Africa is dominated by the massive lowland basin formed by the circuitous route of the powerful Congo River and its tributaries, including both the Kasai and Ubangi rivers, but also takes in several smaller river basins to the northwest (e.g., the Ogooué River of Gabon). Lake Chad and the Bight of Biafra mark the eastern extremity of sub-Saharan West Africa, which stretches westward to the Atlantic Coast of Senegal, and north from the Guinea Coast to the edge of the Sahara Desert. This is a region characterized by low-lying plateaux, through which the Niger River takes a meandering route northeast from Guinea, before turning

Central and West African Middle Stone Age: Geography and Culture, Fig. 1 Africa showing major river and lake systems and the locations of central and West Africa, as based on political boundaries. Sites discussed in the text include *1* Twin Rivers, *2* Kalambo Falls, *3* Kamoa, *4* Lunda Province, *5* Lupemba, *6* Muguruk, *7* Sango Bay and Nsongezi, *8* Katanda, *9* Gombe Point, *10* Okala, *11* Mosumu, *12* Nzako, *13* Shum Laka, *14* Sai Island, *15* Asokrochona and Tema West, *16* Birimi, *17* Anyama, *18* Bété I, and *19* Ounjougou

southeast and finally draining into the Atlantic Ocean in Nigeria.

Serious archaeological interest in the deep prehistory of Central and West Africa began in earnest in the earlier part of the twentieth century; however, a combination of human, ecological, and geomorphological (land form) obstacles has conspired against their continuous and systematic archaeological survey. Limited transport infrastructure, dense rainforest and woodland vegetation, and periodic political upheaval present barriers to most fieldwork projects designed to address specific research questions. Instead, archaeological enquiry and knowledge of prehistoric human presence is generally restricted to locations where modern developments (e.g., roads, settlements, mining operations) enable access. These logistical impediments are made even more severe by tropical African soil conditions and climate. Acidic soils typically cause the rapid decay of plant, animal, and human remains, while monsoon rains remove artifacts from their depositional contexts and in some areas create erosional hiatuses (gaps) in buried cultural sequences. Very little human skeletal material has yet been recovered from Middle Stone Age contexts in Central or West Africa, the archaic *Homo sapiens/Homo heidelbergensis* crania and postcranial fossils from Broken Hill (Zambia) on the margins of Central Africa being one of very few relevant specimens. Additionally, insects and tree roots cause subsurface disturbances, moving artifacts and other materials (e.g., charcoal) up and down in soil profiles (van Noten 1982). Discussed in detail below, these severe post-depositional processes mean archaeologists are still struggling to reconstruct the basic Stone Age cultural sequences, chronologies, and past environments needed to understand prehistoric human activities in time and space. It is only in the last decade that very tentative steps have been taken to start addressing long-standing questions surrounding the behavioral adaptations of MSA hominins in Central and West Africa.

In spite of these problems, important new data on the MSA is still slowly emerging from the central and western parts of sub-Saharan Africa. Since the 1990s, both newly discovered and re-excavated sites have revealed some startling insights into the early technological sophistications of *Homo sapiens*. Finds including 80,000-year-old carved fishing harpoons from the site of Katanda (Yellen et al. 1995) in the eastern Democratic Republic of Congo (DRC) and 270,000-year-old advanced blade tools and modified pigments at Twin Rivers (Zambia) (Barham 2000) are of continent-wide – and arguably also global – significance. The importance attributed to these discoveries stems from their great age, rather than their inherent character alone. Indeed, perhaps more important than any individual discovery has been the fresh chronological context given to Central and West African MSA technologies by very old dates from the sites of Twin Rivers, Kapthurin, Sai Island, and Bété I (Fig. 1). These dated sequences indicate the emergence of distinctive MSA toolkits across these regions by at least 180,000 years ago – and probably earlier than 250–300 thousand years ago – well before the anatomical appearance of *Homo sapiens*.

Dense archaeological literatures exist in both French and English respectively for the Stone Age records of the Francophone and Anglophone countries making up Central and West Africa. Authoritative historical accounts of the archaeological work conducted have been presented by de Maret (1990), Kense (1990) and de Barros (1990) in Robertshaw's *A History of African Archaeology*, however, there has been no truly complete synthesis of work conducted on the MSA for many years. Relatively recent overviews of the state of research have been provided by Barham (2000), Casey (2002), and Cornelissen (2002), while the most up-to-date contribution is that offered by Taylor (2011). This entry aims to outline the current state of archaeological knowledge on the MSA in Central Africa and West Africa. It is structured thematically, according to the principal questions that continue to occupy the attention of researchers.

Identifying Key Issues

Knowledge of the Middle Stone Age in both Central and West Africa remains immature, with current debates still troubled by a lack of intact archaeological sequences and by fundamental

uncertainties over the composition, sequencing, and age of the prehistoric cultures that have been previously recognized and reported. Indeed, as Barham (2001:67) has stated, after 90 years of scientific work, researchers working in these regions are "still in the process of sequence building." While many critical facts remain open to debate, Table 1 provides a generalized scheme of the Stone Age cultures so far identified in Central and West Africa, along with some of their key

Central and West African Middle Stone Age: Geography and Culture, Table 1 Key features of the principal cultures present in the Stone Age archaeological record of Central and West Africa. Note that taphonomic problems mean this generalized scheme remains open to question and, with the exception of new dates, unchanged since the late 1960s. (?) symbol denotes unresolved question, considered likely. (??) symbol denotes unresolved question, considered unlikely

Sequence			Age		Toolkit	Issues
			Previous (^{14}C)	Revised		
YOUNGER ← OLDER	ESA	Final Acheulean	50,000	400,000	Refined: Handaxes Cleavers Small scrapers	Well defined Hand-held technology Present in forested C. & W. Africa??
		Sangoan	Older than 40,000	Older than 250,000	Heavy-duty: Picks Large core axes Choppers Core scrapers	Very poorly defined. Very poorly dated. Hafted?? Forest-adapted?? Present in W. Africa?
	MSA	Lupemban	40.000–15.000	300,000-150,000	Distinctive: Large foliate points Core axes Small points (backed) Blades	Most sites poorly dated. Hafted technology? Hunting? Forest-adapted? Present in W. Africa??
		Lupembo-Tshitolian (SW Central Africa only)	Younger than 25,000	Undated	Small: Foliate points Core axes Backed pieces Tranchets	Very poorly defined Result of mixing? Very poorly dated Woodland adapted? Unknown in W. Africa
	LSA	Local variants; e.g., Tshitolian	Younger than 10,000	Younger than 40,000?	Microlithic, sometimes with: Small points Small core axes Tranchets	Complex halted toolkit Hunting & Gathering Better dated Gradual post-MSA change?

features, as currently known. Tellingly, with the exception of revised dates, this information has remained fundamentally unchanged since the late 1960s.

The 1950s, 1960s, and 1970s witnessed a period of intensive and seemingly productive research that in hindsight can be considered the "golden age" of scientific investigation into the Stone Age archaeology of Central and West Africa. At this time, some of the most preeminent Africanist archaeologists of the twentieth century, including Desmond Clark, Louis Leakey, Georges Mortelmans, and Oliver Davies, undertook excavations and comparative studies on vast scales unknown in more recent decades. At locations across Central and West Africa – for example, in the Dundo region of northeast Angola, on the Kinshasa Plain in the DRC, and at the sites of Kalambo Falls, Zambia, and Asokrochona, Ghana (Fig. 1) – the exposed sections of massive excavated trenches revealed broadly similar successions of post-Acheulean Stone Age industries that formed the basis of an emerging regional cultural sequence for the MSA (de Maret 1990). From older to younger, these cultures were respectively named the Sangoan and the Lupemban and are discussed at length in this entry, while the stone tool types characteristic of these MSA industries are detailed below and shown in Fig. 2. Towards the end of the MSA, the Lupemban was considered to change slowly into a variety of Later Stone Age (LSA) cultures typified by microlithic technologies. The Tshitolian industry is a local variant of the LSA found in the southwestern part of Central Africa and may have developed from an intermediate "Lupembo-Tshitolian" culture containing elements of both late MSA and early LSA technologies (Table 1). The Sangoan, Lupemban, and Tshitolian were, respectively, named after type sites at Sango Bay (Uganda), Lupemba (DRC), and Bena Tshitolo (DRC) where they were first found and defined (Clark 1971).

Since the 1970s, there has been a precipitous decline in fieldwork intensity across Central and West Africa due to the effects of postcolonial political and socioeconomic instability. Of equal, or perhaps even greater, influence has been the recognition of several seemingly insurmountable obstacles that make studying the Stone Age archaeological records of these regions extremely challenging. Discussed in detail below, these brakes on data collection and the progress of research mean that the key questions about the MSA of Central and West Africa that emerged in the mid-twentieth century have remained unresolved for more than 50 years and are still current. These long-standing and unsettled issues provide the essential structure of the remainder of this entry. Issues focusing on the nature of the Central and West African Stone Age records, their characteristic MSA industries, and chronology are discussed first. Following this, key theoretical issues centering on the possible adaptations represented by these cultures are outlined. The issues addressed can be summarized as follows:

- What is the general sequence of MSA cultures in Central Africa and West Africa, and how can Sangoan and Lupemban lithic industries be defined?
- How old is the MSA in Central and West Africa, and for how long did it last?
- Were Sangoan and Lupemban stone tools routinely hafted for use?
- Were Sangoan and Lupemban technologies adapted for hunting and gathering in woodland and rainforest environments?

Central and West African MSA Sequences: Defining the Sangoan and Lupemban

Archaeological fieldwork projects of the 1950s and 1960s attempted to make real progress towards the construction of a reliable Stone Age sequence for Central and West Africa. The Sangoan industry was found to overlie the Acheulean at the sites of Nsongezi (Uganda), Asokochona (Ghana), and Kalambo Falls (Zambia). In a remarkable departure from the refined symmetry of late Acheulean hand axes, the Sangoan was characterized as a rugged toolkit dominated by thick and heavy biface tools, including core axes, picks, choppers, and core scrapers, which were shaped roughly by striking a few flakes from large cobbles of tool stone. An

example of a Sangoan pick is shown in Fig. 2: 1. The Lupemban was found to sit above the Sangoan at Kalambo Falls (Zambia), and was said to include refined bifacial lanceolate points, core axes, Levallois points, and blade tools. A range of implements typical of the Lupemban are shown in Fig. 2: 2–6; 8–9. At sites across Central Africa, LSA assemblages were found to lie above MSA industries and were identified as informal quartz-based industries, or as "Tshitolian" toolkits based on the continuation of bifaces in smaller, more delicate forms, as well as segments, *petit tranchets*, backed pieces, and points finely retouched by pressure technique. The absence of undisturbed archaeological sequences spanning the period between the Lupemban and the LSA led to speculation that over time Lupemban technologies in South West Central Africa gradually phased into the Tshitolian, a change in which Lupemban tools became smaller and more refined, with toolkits featuring an increased number of Tshitolian-type *petit tranchet* (Fig. 2: 7) and microlithic elements. By the close of the 1960s, researchers might reasonably have concluded that they were close to resolving the essential makeup of Sangoan and Lupemban industries and to defining their place in space and time (Table 1). Subsequent research developments have shown such a view to be overly optimistic.

The work conducted across Central Africa during this period built on the fieldwork undertaken in the 1920s by Jean Colette, at a site today known as Gombe Point. This site, located on the banks of the Congo River in modern-day Kinshasa (DRC), revealed a succession of cultures that formed the basis for the first detailed framework for the Stone Age in Central Africa (Clark 1971). At the base of the excavated sediments was a culture Colette called the Kalinian that was dominated by large, minimally worked Acheulean-like bifacial implements, along with some flake tools. Above this, a

Central and West African Middle Stone Age: Geography and Culture, Fig. 2 Lithic artifacts of the Central and West African Middle Stone Age: *1*large, Sangoan-type pick, Camafufo, Angola; *2* prepared core (PCT) point, *3* convergent PCT point with facetted platform, *4* blade with lateral retouch ("backing"), *5*double-ended bifacial lanceolate point of Lupemban-type, *6* bifacial core axe of Lupemban-type, *7* tranchet point, *8* small PCT point, and *9* prepared core suitable for Levallois flake removals. No *1* from Camafufo, Angola; Nos *2–4* and *8–9* from Kalambo Falls, Zambia; No *5* from Gombe Point, DRC; No *7* from Twin Rivers, Zambia

culture characterized by a smaller, flake-based technology consistent with the Middle Stone Age was recovered alongside refined, daggerlike bifaces, to which the name Djokocian was applied. Higher up in the sediments, an assemblage containing microlithic artifacts of Later Stone Age type was named the Ndolian. Despite the different names given to them at that earlier time, these stone tool assemblages remain roughly equivalent to the Sangoan, Lupemban, and Tshitolian industries, as known since the 1950s (Barham 2001). Re-excavation of this important sequence by Daniel Cahen in the mid-1970s, however, identified a range of critical problems that call into question the vast majority of work conducted across Central and West Africa in preceding decades. The impact of this research is still felt today by archaeologists who continue to research the MSA in these regions.

Jean Colette accurately reported that the stone tool industries at Gombe Point rest beneath the modern soil surface in a single, approximately 7 m thick layer of sediment. Like Colette, Cahen's work (1978) identified multiple stone tool horizons in this soil layer but, crucially, he found that refitting stone tools (which must have been produced at the same time, during a single prehistoric stone tool knapping event) were vertically separated by up to 1.5 m in the sequence. This observation showed that severe subsurface soil movements resulting from bioturbation – the mixing of sediments by tree roots and insects – had moved artifacts up and down in the sequence since their ancient deposition, blending tools of different ages together into what *appear* to be distinct cultures in different stratigraphic positions (Cahen and Moeyersons 1977). The importance of this finding cannot be overstated; rather than accurately reflecting a series of changes in technologies over time whose study could reveal insights into prehistoric human behaviors, the Stone Age "industries" at Gombe Point instead result from the mixing of once discrete cultures into artificial levels of Stone Age material. Called "stone lines," these accumulations of mixed archaeological material have very low stratigraphic and cultural integrity and prevent the reliable definition and comparison of prehistoric stone tool industries over time and space (Moeyersons 1978). Similar processes also move other materials – including charcoal and pollen – that are useful both for dating and for reconstructing prehistoric environments, such that their association with particular stone tool assemblages cannot be determined reliably. This has implications for understanding the age and environmental context of MSA industries, issues that are explored later in this entry.

Revision of the Gombe Point sequence showed that the time-depth relationships that underpin the principle of stratification (in which the more deeply buried layers in a sequence are relatively older, and those nearer the surface are relatively younger) are confounded at this site. This understanding led Cahen to conclude that the integrity of the archaeological record across Central and West Africa may be so poor that only two broad cultures can be firmly distinguished in these regions – the Acheulean and a subsequent "Post-Acheulean Industrial Complex." According to this view, distinct Sangoan and Lupemban industries, as previously identified and described within the Congo basin, are erroneous and do not reflect prehistoric reality. More recently, "stone lines" have been seen to characterize the archaeological sequences of a large number of Central and West African sites, including Asokrochona, Chaminade, Kamoa, Mosumu, Nsongezi, and several sites located on the Kinshasa Plain (Fig. 1). Identifying the exact processes that cause buried lithic artifacts and other materials to disperse and reform as stone lines has proven difficult. Shifting sandy soils, in combination with tree-root activity (Moeyersons 1978), erosion (Schwartz 1996), and burrowing termites (McBrearty 1990), have been the principle explanatory factors forwarded, but should not be considered as mutually exclusive (Mercader et al. 2002).

Knowledge of the Sangoan and Lupemban MSA is now widely recognized to be extremely poor. Numerous MSA sites exposed by diamond mining in the Dundo region of Angola, including Musolexi, Camafufo, and Catongula (Clark 1963), provide much-needed information about the Stone Age in the southern part of the Congo

basin, but here Sangoan and Lupemban artifacts are found mixed together in a gravel layer and cannot be reliably separated based on stratigraphy. Knowledge of the MSA on the northern edge of the Congo basin is particularly poor, with a few disturbed sites studied by Bayle des Hermens (1975) providing essential data. Similar mixed aggregates also typify the MSA recovered from the "N" and "O" horizons at Nsongezi while, despite being in better stratigraphic context, McBrearty (1988) could not be completely confident in separating Sangoan- and Lupemban-like assemblages at Muguruk, preferring instead to describe them using the compound name "Sangoan–Lupemban." At the site of Kamoa, no Sangoan material is present at all – rather, an occupation gap or erosional phase is indicated in which the Acheulean is followed by a small, probable Lupemban assemblage in insecure context (Cahen 1975). In contrast to these mixed gravel and surface accumulations, a series of sites on the Kinshasa Plain (near to Gombe Point) have revealed deep sequences of poorly stratified sandy soils, in which van Moorsel (1968) observed subtle changes in Sangoan and Lupemban technologies over time. Based on an apparent trend towards smaller and more refined biface tool forms, Clark (2001) and Mortelmans (1957) both argued for the existence of discrete Lower (older) and Upper (younger) phases within the Sangoan and Lupemban. Even at the well-stratified site of Kalambo Falls (see below), however, the stratigraphic record for the Central African MSA is simply too coarse-grained to allow the secure identification of subtle technological changes over time. Until a more intact, high-resolution sequence of Sangoan and/or Lupemban material is found, the existence and nature of change within these cultures will remain speculative.

In spite of these very significant problems, several researchers continue to see meaningful similarities between the more heavily disturbed Middle Stone Age sites found in the tropical, forested interior of lowland Central and West Africa and a handful of less-disturbed archaeological sequences excavated on their woodland margins. Located on the periphery of Central Africa, sites including Muguruk, Twin Rivers, and Kalambo Falls provide evidence that the general regional sequence of Acheulean–Sangoan–Lupemban grading into LSA is essentially accurate. At the southern end of Lake Tanganyika in northeastern Zambia, the site of Kalambo Falls in particular provides a key sequence for the Central African MSA. Here, overlying a series of stratified Acheulean layers with abundant hand axes, cleavers, and rarely preserved organic materials, archaeological horizons representing the Sangoan and Lupemban are identifiable. Critically, these are separated from the Acheulean, and from one another, by sandy horizons that ensure only extremely limited mixing has occurred between the industries (Clark 2001). That the essential integrity of this sequence has been retained is also supported by technological differences between the two excavated technologies. Low numbers of characteristic MSA artifacts such as Levallois points and blade tools are found in the Sangoan horizons, which are contrasted in the Lupemban levels by an abundance of MSA tools made by Levallois methods, alongside bifacial, blade, and backed blade tools. Better, but still imperfect, stratigraphic control at these peripheral sites indicates that, although heavily disturbed, difficult to define or date, and poorly understood across most of Central and West Africa, Sangoan and Lupemban MSA technologies *are* valid prehistoric cultures.

Since the mid-1990s, new excavations at several sites located across Central and West Africa, including Twin Rivers, Sai Island, Mosumu, Birimi, Ounjougou, and Bété I, have provided new insights and a more positive foundation upon which future MSA research might build. At the collapsed cave of Twin Rivers, the Lupemban is capped above and below by layers of limestone that isolate the industry from any older or younger cultures and includes advanced backed blade technologies (Barham 2002a) that are the subject of detailed discussion later in this entry. This site, along with Sai Island, has also proven vital as a datable sequence enabling the construction of a more accurate chronology for the central African MSA, as discussed below. Sai Island is located far outside the geographical zone

typically associated with the Central and West African MSA but has revealed a deep stratigraphic sequence that incorporates lithic assemblages, separated by sterile sands, that bear surprising affinities to the Sangoan and Lupemban (van Peer et al. 2004). When more fully understood, this site promises to clarify the nature and degree of any connection between the MSA in Central and West Africa, and that of North and Saharan Africa, especially in terms of hominin migrations and or social and cultural links. Work at Mosumu has provided important new information about the MSA in Atlantic Central Africa. Here, a problematic stone-line context includes an MSA–LSA assemblage with small bifacial foliate points that may reflect a late expression of the Lupemban. The Birimi site (Ghana) fills an important geographical gap between Central and West Africa. As reported to date, this site includes a small series of generic Levallois-type tools that is complemented by a few Lupemban-like lanceolate artifacts, and may form an important point of comparison between the two regions. Further to the West, Ounjougou and Bété I have yielded precious, datable sequences for the MSA in West Africa and are discussed below.

Dating the MSA in Central and West Africa

Middle Stone Age industries across sub-Saharan Africa were historically considered to be around 40–12 thousand years old, based on radiocarbon (^{14}C) dates taken on buried charcoal samples. Developed in the 1950s, this scientific dating tool was applied widely to date Acheulean and MSA industries throughout the 1960s, 1970s, and 1980s and indicated that MSA technologies were a relatively recent and short-lived technological interlude (perhaps lasting for less than 40,000 years) prior to the appearance of microlithic LSA cultures around 10,000 years ago. Once considered beyond doubt, this carbon-based time span for the MSA has, however, been comprehensively reassessed in the last 30 years. It is now recognized that even modern AMS^{14}C dating methods are incapable of accurately ageing carbon samples if the charcoal has a true age greater than about 45,000 years; the application of^{14}C dating methods to materials older than this results only in dates that agree with this technical limit. The development and refinement during the 1980s, 1990s, and 2000s of a range of new scientific dating techniques with greater time depth has since yielded much earlier dates for the emergence of MSA technologies across sub-Saharan Africa. These generally agree that MSA toolkits appeared during the period 400–200 thousand years ago and show that they continued in use until roughly 45 thousand years ago (McBrearty and Brooks 2000). Sangoan and Lupemban MSA industries of Central and West Africa are now associated with an emerging chronology within this date range and, in this context, can be considered directly relevant to understanding the changes in hominin brains and behaviors that underpin the evolution of *Homo sapiens*.

The stratigraphic inadequacies of the Central and West African Stone Age records (as discussed above) create major problems for constructing cultural and technological sequences but also for building absolute chronologies based on scientific dating methods; most sites thus remain undated. For some researchers, particularly those working in the forested interior of these regions, the difficulty of applying dating techniques other than radiocarbon means the^{14}C database still forms the only chronological framework (e.g., Cornelissen 2002). However, in addition to the technical limits associated with these dates, the vertical movement of artifacts and charcoal samples in stratigraphic sequences means the association of dated samples with particular tool horizons is frequently unreliable. This problem is particularly acute in the lowland interior of Central Africa, where several sites, including Gombe Point, Mosumu, and Dimba, exhibit profiles in which dates do not consistently increase in age with depth, showing significant vertical movement has occurred (Cahen et al. 1983). For all these reasons, and in light of a growing body of much older dates from the margins of Central and West Africa and from Southern and East Africa, most researchers now consider the radiocarbon dating record for the MSA to be essentially redundant and that sites to which only this technique has been applied remain effectively undated (Barham 2001). In spite of this understanding, the

continued use of radiocarbon dates in some current research on the Central and West African MSA warrants their presentation here.

The radiocarbon record takes in sites and sequences found across most parts of Central and West Africa, from within the Congo basin, on its southern and eastern margins, as well as many West African sites. In addition to the problematic dates from Gombe Point, dated MSA materials attributed to the Sangoan and Lupemban at the sites of Basoko, Belgika and Lemba on the Kinshasa Plain (van Moorsel 1968) are also found in similarly disturbed "stone-line" contexts. Radiocarbon dates for the Sangoan here range from >26,000 to >30,000 years BP (before present), while estimates for the age of the Lupemban vary between 12,230 ± 250, 15,080 ± 480, and >30,000 years BP. The Gabonese site of Okala (Clist 1997) stands out in Atlantic West Central Africa as a site with a more intact, dated stratigraphy. Here, a horizon of charcoal resting on clay has recently been radiocarbon dated to 39,690 ± 670 BP and >40,000 years BP, indicating a minimum age for the small collection of generic and probably relatively late MSA artifacts found in association. In West Africa, absolute dates for the MSA, even by radiocarbon, are extremely rare, but estimates based on stratigraphic grounds have often registered more recent age estimates than those from Central Africa. At the two nearby sites of Asokrochona and Tema II (Ghana), Sangoan occurrences are present at the base and upper part of a laterite gravel layer considered by Nygaard and Talbot (1984) to have formed around 20,000 years ago, the relative ages of the assemblages being estimated as 13–20 thousand years old and 20–25 thousand years old, respectively. At Anyama (Ivory Coast), a Sangoan assemblage with both heavy-duty and Levallois elements remains undated.

On the southern margin of the Congo basin, radiocarbon dates for the Sangoan and Lupemban are similarly problematic, but some sites are now revealing markedly earlier dates for these MSA industries. In northern Angola, a series of dates have provided age estimates of 38,000 ± 2500, >34, and >40 thousand years BP for the earliest "Sangoan/Lower Lupemban" industry and 14,503 ± 560 years BP for the "Upper Lupemban/Lupembo-Tshitolian" industry, but based on comparisons with other sites, dates for the earlier part of this record are certainly far too young. Twin Rivers (Zambia) is the only site across Central or West Africa to which both old and new dating techniques have been applied to the same MSA sequence and provide a case study for their effects on resulting chronologies. A Lupemban assemblage, here incorporated in limestone breccias, was twice dated in the 1960s by radiocarbon technique, yielding results of 22,800 ± 1,000 BP and >33,200 years BP. However, the redating of the stratigraphic profile by uranium-series technique in the 1990s established a secure time span of 265–170 thousand years BP for these same layers, highlighting both the potential difference in dating estimates between radiocarbon and longer-ranged techniques and the true antiquity of the Lupemban MSA on the southern margin of Central Africa (Barham 2001). Kalambo Falls, with its far larger yet technologically similar Lupemban MSA assemblage, probably represents an MSA record of comparable age to that at Twin Rivers but has yet to be dated reliably using methods other than radiocarbon. The existing Kalambo Falls radiocarbon chronology compares well with ^{14}C dates from elsewhere on the margins of Central Africa (e.g., northern Angola), the Sangoan levels ranging between >40 and 43 thousand years BP, and the Lupemban rubble horizons falling in the range 27–31 thousand years BP. These estimates are also best treated as far too young, however, particularly given that amino acid racemization dates on Acheulean age wood from the same sequence, have yielded an age of approximately 190 thousand years BP for the latest Acheulean (Clark 2001). At Mumbwa Caves (Zambia), a sequence extending back 170 thousand years includes generic MSA assemblages but lacks any elements distinctive of the Sangoan or Lupemban, further supporting an early time span for these industries in south-central Africa (Barham 2000).

Relevant dated sites exist elsewhere on and beyond the margins of Central Africa. Sai Island (Sudan) is located far outside Central Africa (Fig. 1) but includes in stratified sands

assemblages showing affinities to the Sangoan and Lupemban (van Peer et al. 2004). Provisional optically stimulated luminescence (OSL) dating estimates of 182 ± 20 thousand years BP for sands immediately above the Sangoan assemblage provide a minimum age for this industry which, in combination with a date of 152 ± 10 thousand years BP from sands above the overlying Lupemban-like assemblage, provides an effective time span of >180–150 thousand years for the MSA at this site. While it remains unclear how representative these assemblages are of the MSA in Central and West Africa, they share certain technological features, including the occurrence of distinctive core axes. The Kapthurin Formation (Kenya) provides a key sequence for the Acheulean–MSA transition, since it shows the repeated appearance and disappearance of bifacial, Levallois, and blade-based technologies over time, indicating that a simple model in which toolmaking traditions are sequentially replaced over time may not apply here. Within the excavated sequence, assemblages with Sangoan-like heavy-duty picks predate 285,000 years ago (Tryon and McBrearty 2002), and are broadly coincident with dates for the origins of the Central African MSA in south-central Africa.

In West Africa, very few MSA sites have yet been dated using modern techniques capable of accurately resolving chronologies beyond 40,000 years. Bété I (Ivory Coast) records a series of Sangoan assemblages made up of characteristic picks, core axes, and bifaces that have been dated by thermoluminescence (TL) technique to 254 ± 51 thousand years BP (Liubin and Guédé 2000). Though associated with a large range of error, this date demonstrates the early emergence of MSA technologies in West Africa. Conversely, other dated West African sites have so far revealed more recent dates for the emergence of the MSA here. Currently one of the more intriguing MSA sites in West Africa is Oungoujou (Mali), which actually consists of an exposed landscape incorporating numerous profiles. The post-Acheulean sequence here includes an industry in Unit 2 that is typified by bifacial tools dated between 60 and 80 thousand years ago, followed by the development of blade technology at 60,000 years ago, and, only later, between 50 and 55 thousand years ago, the appearance of Levallois flaking strategies (Robert et al. 2003). Distinctive Sangoan and Lupemban toolkits do not feature here, while the sequencing of different technologies and their relatively late appearance in comparison to emerging dates for the MSA in Central Africa is difficult to account for at present. At Birimi (Ghana), surprisingly late dates of 23.6 ± 2.9 thousand years BP and 40.8 ± 11.8 thousand years BP for sediments encapsulating an MSA assemblage with possible, yet unconfirmed, similarities to the Lupemban industry might be explained as relating to a very late expression of the MSA but alternatively perhaps hint at the persistence of these technologies over time (Casey 2002). The overlap of these dates with problematic ^{14}C dates for the Sangoan and Lupemban MSA elsewhere in Central and West Africa might reflect the genuine later appearance of the MSA in this part of West Africa, but any interpretation should be drawn cautiously, given the wide error range associated with the lower date.

Currently available dates for the MSA in Central and West Africa are sparse and highly variable, reflecting technical differences in the dating methods applied and the difficulties involved in applying techniques other than radiocarbon. A growing body of data is, however, beginning to highlight that MSA industries across these regions appeared far earlier than was previously understood on the basis of the radiocarbon dating record. It is notable, however, that with the possible exception of Bété I, all of the very old estimates (Twin Rivers, Sai Island, Kapthurin) relate to sequences found on the fringes of these regions, and it is therefore possible that the numerous Sangoan and Lupemban sites known from the interior of the Congo basin are in fact far more recent in age. The absence of well-dated sites bridging the gap between these old chronologies and those derived through radiocarbon technique makes it particularly difficult to pin down when Central and West African MSA technologies began to transition into LSA industries or for how long the MSA lasted in these regions. On

the balance of present evidence, Sangoan and Lupemban MSA technologies, when taken as a whole, seem to have first appeared sometime around 400,000 years ago and to have continued in use perhaps until around 40–50 thousand years ago. Although certainly in need of verification through the dating of many more sites from across the vast geographic range of Central and West Africa, this time span fits well with the known age of the MSA across Southern and East Africa.

Complexity in Tool Manufacture and Use

Middle Stone Age technologies from across sub-Saharan Africa have long been considered to reflect the hafting of stone tools into handles, as composite implements used for hunting and gathering (e.g., Clark 1959). The stone-tipped hunting spear is perhaps the most familiar example of such an implement and may have its earliest origins in the distinctive stone "points" that characterize regional MSA industries (Fig. 2: 2–3 and 8). In terms of their size, shape, and method of manufacture, points and other artifacts made by the Levallois technique mark a departure from preceding Acheulean biface tools. Alongside observations drawn from contemporary and historical stone tool-using hunter-gatherer societies, modern replication experiments back up the concept that MSA-type artifacts can be usefully deployed as a range of hafted foraging implements. Other tool types, including blades and deliberately blunted ("backed") blades (Fig. 2: 4), can be similarly hafted but moreover have traditionally been considered by archaeologists to be advanced LSA technologies made only by *Homo sapiens*. The identification of these artifact types in many MSA industries – including some Lupemban assemblages predating the appearance of anatomical *Homo sapiens* at 200,000 years ago – suggests the early evolution of technologically and behaviorally complex adaptations by MSA Central African hominins.

The advent of specialist projectile weapons, handled axes and adzes, and other complex technologies including nets, traps, and fishing equipment marks a fundamental change in human interactions with the environment. They confer an array of advantages to hunter-gatherers: providing a more effective and safe way to exploit existing sources of food (e.g., the more successful hunting of large, dangerous animals from a distance) and enabling the extraction of a wide range of otherwise inaccessible resources (e.g., hard woods, buried roots and tubers, tree-dwelling animals, fish), thus presenting a means to settle long term in environments previously inhospitable for human foragers, including highlands, deserts, and rainforests. Stone Age researchers have recently refocused attention on the implications that multi-component tool construction and utilization have for the evolution of hominin intelligence. This is based on the understanding that crafting a composite implement requires a well-developed imaginative ability (visualization of completed tool designed for a specific task), detailed environmental knowledge (selection of multiple organic materials that can be combined), sophisticated forward planning skills (preparation of each collected material to alter its individual properties), and technical expertise (assembly of materials to create tool form appropriate to task). The design and manufacture of complicated multi-element implements for an anticipated, specialized future use is now commonly recognized as indicating "modern" foraging behavior and mental abilities synonymous with *Homo sapiens*.

Except in extremely rare circumstances, the organic parts of composite implements degrade rapidly and are not seen in the archaeological record, and it has thus proven very difficult to provide definitive evidence of complex hafted tool manufacture and use in the MSA. Because they are typically used in remote locations and made only of soft organic materials, traps are virtually invisible in the archaeological record but, given the right soil conditions, the more durable organic parts of fishing gear can be preserved. Direct evidence of the use of bespoke, intricate organic implements in the Central African MSA comes from the site of Katanda on the western edge of the Great Rift Valley. In the late 1980s, an international team of archaeologists uncovered two carefully shaped, carved bone points with barbs in double rows (Yellen et al. 1995) in association with a generic MSA lithic assemblage lacking any clear affinities to the Sangoan or

Lupemban. On first sight, the complexity of these unmistakable fishing harpoons might be assumed to reflect a very late MSA, or even a more recent LSA technology, but dating by optically stimulated luminescence (OSL) has confirmed that they are at least 80,000 years old. Unique across sub-Saharan Africa, these ornate MSA fishing tools highlight that complex toolmaking abilities and foraging strategies were likely well established across much of Central Africa by this time, and probably much earlier.

At most MSA sites, the analysis of stone artifacts offers the only method to identify complex tool use, and in recent years this field of study has been revolutionized by developments in the practices of lithic use-wear analysis and residue analysis. These techniques employ microscopes to examine stone artifact edges for traces of damage and adhering organic particles resulting from prehistoric tool use, including contact with handles (Barham and Mitchell 2008: 277–8). In Southern and East Africa, some well-preserved sites (e.g., Sibudu Cave in KwaZulu Natal, South Africa) have revealed numerous MSA points and backed pieces with distinctive edge damage, showing where they were routinely attached to handles (which have themselves long since perished) for use as hunting weapons. While many LSA and MSA cultures from sub-Saharan Africa are now well understood to include intricate, multi-component technologies that were employed to hunt and gather, the evidence from Central and West Africa is still mostly circumstantial. In the Congo basin, Tshitolian LSA toolkits reflect an established hunting, gathering, and fishing culture based on composite tools; but the absence of any well-preserved MSA sites with intact stratigraphies across Central and West Africa places limits on the identification of complex hafted technologies and foraging behaviors in the Sangoan and Lupemban.

The large, roughly made bifacial tools characteristic of the earliest Central and West African MSA – the Sangoan – have been considered likely candidates for hafting since the 1950s (Clark 1959), but compelling evidence has only recently been reported. At Sai Island, use-wear analysis has shown that 27 Sangoan-type core axes were inserted into handles before being used in digging activities (van Peer et al. 2004). Given its location in northeast Africa and the vast area across which the Sangoan was made and used (Fig. 1), it remains unclear how representative this assemblage is of the industry. Larger Sangoan assemblages recovered from other sites, including Kalambo Falls and Bété I, lack clear evidence of stone tools made by the Levallois technique and cast doubt on the concept that Sangoan stone tools were made with the intention of hafting. In contrast, the wide range of stone artifact types present in the Lupemban toolkit may have provided a suitable basis for the manufacture and deployment of composite hunting and gathering implements. Finely crafted lanceolate points are the defining feature of the Lupemban toolkit (Fig. 3) and have often been theorized to have been hafted as the tips of hunting spears. Composite projectile functions have also been proposed for other tools such as small Levallois points and deliberately backed blades, while well-made Lupemban core axes have frequently been hypothesized to be the working ends of axes and adzes for working wood. However, the only systematic use-wear analysis of confirmed Lupemban tools (Taylor 2011) has

Central and West African Middle Stone Age: Geography and Culture, Fig. 3 Three views of a bifacially flaked lanceolate point excavated from Kalambo Falls, Zambia. These tools have been repeatedly been hypothesized to have functioned as the stone tips of composite hunting spears as part of a rainforest-adapted toolkit

so far found only limited evidence supporting the use of core axes as hafted heavy-duty woodworking implements.

At present, direct evidence linking the Sangoan and Lupemban to sophisticated hunting and gathering subsistence strategies is limited, but the balance of available data supports the concept that, rather than the Sangoan, the Lupemban MSA may reflect the first widespread adoption of composite hunting and gathering technologies. Some types of heavy-duty biface present in the Sangoan were probably hafted, but the industry lacks a broader range of stone tools suitable as part of a diverse composite toolkit incorporating projectile armatures. In contrast, the Lupemban includes heavy-duty and light-duty stone tools apparently designed for composite use, from which a specialist composite toolkit might be created. Taken alongside early dates for the Lupemban derived from Twin Rivers (see above), this stone tool industry may represent one of the earliest hafted technologies, anywhere. In addition, the occurrence of small numbers of advanced backed blades (Barham 2002a), alongside large quantities of yellow, red, and brown ochreous pigment that does not occur locally (Barham 2002b), indicates that the Stone Age people who occupied the Twin Rivers cave between 265 and 170 thousand years ago were undertaking cognitively complex and symbolic activities, including the construction of advanced LSA-like composite armatures and perhaps body decoration, well before the emergence of anatomically modern *Homo sapiens*.

Environmental Adaptations

Sangoan and Lupemban industries of the Central and West African MSA have been persistently thought of as prehistoric adaptations for foraging in dense jungle and woodland environments, which are today widespread across these regions. This concept originated with Desmond Clark (1959) and matured during the 1960s as researchers began to investigate seriously the patterning of MSA cultures in time and space and tried to explain the distinctive features of their toolkits. The similarity of heavy-duty biface tools in Sangoan and Lupemban assemblages to implements used for woodworking by modern stone tool-using hunter-gatherer societies partly inspired this hypothesis. The main observation upholding it is the apparent correlation between the location of Sangoan and Lupemban sites, and the modern distribution of rainforest and thick woodland ecosystems, as shown in Fig. 4. Both industries are well represented in the lowland rainforests and river basins of Central and West Africa, even in spite of the fact that survey and fieldwork has been carried out patchily. Acheulean hand axes and cleavers are effectively absent from these same areas but are present across Southern and East Africa, and in North and Saharan Africa, suggesting that MSA technologies (e.g., specialized hunting weapons, traps) and sophisticated hunting and gathering behaviors (e.g., cooperative hunting) played a vital role in the successful settlement of these environments (Barham 2001).

The colonization of new landscapes and environments such as remote highlands and islands, sparse deserts, and densely vegetated woodlands and rainforests signifies an enhanced ability to exploit nature. In comparison to savanna grasslands and light woodlands, access to the resources and foods needed by mobile hunter-gatherers (e.g., fresh water, protein, carbohydrates, minerals) is recognized to be extremely challenging in these ecological settings. Critical resources are generally either rare or occur in limited amounts but, moreover, are restricted to specific locations, unevenly distributed, and unpredictable, making them very difficult to obtain. Long-term survival in such resource-poor conditions is only possible by harnessing specialized extractive hunting and gathering technologies (a variety of dedicated projectile weapons, animal traps, etc.), putting into practice detailed ecological knowledge (e.g., the systematic seasonal exploitation of scattered foods and materials), and by establishing social networks (i.e., contact with other foraging groups to maintain food security) and cooperative behaviors (e.g., organized group hunting). The ability of hunter-gatherers to disperse into, and permanently settle, very challenging landscapes and environments – including rainforests – requires a degree of sophistication in foraging behaviors and mental capabilities matching those of *Homo sapiens*.

Central and West African Middle Stone Age: Geography and Culture, Fig. 4 The distribution of certain and uncertain Sangoan and Lupemban MSA sites in central and West Africa, as recognized in the 1960s. Shown with major river and lake systems of Africa and the contemporary extent of rainforest and woodland ecosystems

Although often thought to be lush places rich in large animals, edible plants, fruits and nuts, dense rainforests, and woodland environments in fact present natural barriers to hunter-gatherers. Barham (2001) has stressed that forest animals including tree-dwelling primates, duikers, and forest elephant can be hunted or captured only using specialized projectile technologies, traps, and nets in organized cooperative activities. Nutritious plant matter is surprisingly sparse, meaning humans must compete with other animals for access to tall fruiting trees and underground roots and tubers. Indeed, Headland and Bailey (1991), in their study of contemporary hunter-gatherers living in Central African rainforests, argued that energy-rich carbohydrates occur so rarely that even in modern times human foragers can live in jungles only by supplementing their hunter-gatherer diet with yams traded from local farming communities. Their analysis completely excludes the possibility that Stone Age foragers could have subsisted within the Central African rainforest belt; however, more recent anthropological and archaeological research has cast doubt on this extreme view. Excavations in the Ituri rainforest in the eastern part of the Congo basin (DRC) show this area was occupied by LSA hunters and gatherers 18,000 years ago, well before the emergence of farming (Mercader et al. 2000). Similarly flexible and sophisticated composite Sangoan and Lupemban technologies (see above) may reflect an earlier MSA origin for the presence of mobile human foragers in Central and West African rainforests.

Evidence for rainforest and woodland foraging in the MSA of Central and West Africa is problematic and still largely circumstantial. Although Sangoan and Lupemban cultures are seemingly associated with these vegetation zones today (Fig. 4), this same correlation did not necessarily hold true during the Stone Age. Central and West African environments are known from polar ice cores in the past to have undergone dramatic shifts in size and position as global climate has cycled between cool, dry glacial phases ("ice ages") and warm, wet interglacial phases in which conditions were broadly similar to today. Lasting for approximately 100,000 years, these periods are known as marine isotope stages (MIS). Supplementing this global climatic record, long pollen sequences cored from the Atlantic Ocean floor and deep lake sediments provide a record of regional vegetation change in Central and West Africa. Typically, interglacial stage vegetation consisted of a rainforest and woodland belt similar to that recorded for the last 10,000 years (the Holocene), while the dry climate of global glacial stages caused the severe contraction and breakup of these environments into localized pockets, separated by expansive savanna grasslands (Dupont et al. 2000). Modelling past vegetation cover in coastal West Africa is a particular challenge, since fluctuating aridity is known to have caused major and rapid spatial rearrangements to environments not only during the last interglacial–glacial–interglacial cycle centering on the extremely dry conditions of the Last Glacial Maximum (LGM) but also during the Holocene. These regional records of climate and vegetation are also not currently refined enough to allow the distribution of African environments in high resolution before about 25,000 years ago which, in combination with the poor dating record available for Sangoan and Lupemban industries (discussed above), prevents the definitive association of archaeological sites with particular ecologies.

In addition to these global and regional climate and environment records, site sequences preserving animal bones and/or pollen alongside horizons of stone artifacts have sometimes provided local detail of Sangoan and Lupemban flora and fauna. As highlighted earlier in this entry, however, faunal remains are extremely rare at Central and West African MSA sites; indeed, only two examples are currently known: Simbi in western Kenya and Twin Rivers in Zambia. The position of these sites on Central Africa's periphery perhaps begs the question of how well they represent Sangoan or Lupemban industries as a whole. Charcoal and pollen are more frequently preserved; however, acute subsurface disturbance to the record means the stratigraphic position of buried materials and their relationship with particular stone industries is seldom reliable (van Noten 1982).

Very few Sangoan sites have revealed environmental evidence of any kind, with the key sites in

this regard being Simbi and Kalambo Falls, on Central Africa's margins. The large Sangoan-type bifaces and flake tools from Simbi are associated with a substantial bone assemblage consisting of various grazing herbivore species reflecting an open savanna or lightly wooded habitat (McBrearty 1992). At Kalambo Falls, a reliable pollen sequence shows the persistence of deciduous woodlands during the site's use by late Acheulean and Sangoan toolmakers (Clark 2001). Less secure evidence comes from several sites in lowland Central and West Africa. Both Asokrochona and Tema (Ghana) have revealed Sangoan-like assemblages in "stone lines" that, although today found within areas of mosaic rainforest, woodlands, and grasslands, were likely located in dense woodland environments (though not rainforests) during the MSA. A possible Sangoan component in the basal layers at Njuinye (Cameroon) may have been made and used in a forest setting, given that a pollen core from 50 km distant Lake Barombi Mbo records the presence of forest species in the local area throughout the last 28,000 years (Mercader 2002). The apparent persistence of this vegetation through the extreme dry of the LGM suggests forests may have been a consistent feature here during earlier arid phases.

Environmental evidence derived from Lupemban site sequences is similarly meager and problematic. The small and fragmentary bone assemblage at Twin Rivers suggests Lupemban occupation of the southern part of Central Africa coincided with open woodland or grassland conditions (Barham 2000), while 850 km to the northeast, Kalambo Falls bears witness to a massive Lupemban assemblage dominated by bifaces, Levallois and blade tools, and a solid pollen sequence showing the endurance of woodlands throughout the late Acheulean and MSA. At Mufo in northeastern Angola, reworked gravels containing a later Lupemban or Lupembo-Tshitolian assemblage incorporates sparse grass pollen and charcoal hinting at open savanna conditions. In lowland Central Africa, pollen from within the "stone lines" at Mosumu and Ndjole provides some limited evidence for the use of Lupemban technology in humid rainforest habitats, but these sites have clearly suffered extensive subsurface disturbance.

The poverty of faunal and pollen records for the Central and West African MSA underscores just how little is definitively known about environmental adaptations. Current evidence suggests Sangoan and Lupemban industries may relate to a range of environments, including open grasslands, dense woodlands, and forests, but with few exceptions this evidence must be treated with great caution owing to stratigraphic disturbances. Perhaps the strongest indication of a specialized woodland and jungle adaptation remains the apparent general correlation of MSA sites with the regions of Africa prone to the growth of dense vegetation (Fig. 4). The Lupemban in particular seems to offer a range of stone artifact types suitable for the construction of composite tools such as woodworking and projectile weapons that might have enabled the settlement of these environments. If the early dates for the industry at Twin Rivers are representative of the age of the MSA Lupemban across Central and West Africa, then the first settlement of the rainforest belt may have been undertaken by pre-*sapiens* hominins, with important implications for understanding the evolution of human intelligence and social behaviors in sub-Saharan Africa.

Future Directions

This entry highlights that the MSA record of Central and West Africa remains very poorly known in comparison to the Stone Age records of Southern and East Africa and North and Saharan Africa. These regions are beset by a range of stratigraphic problems that have inhibited the construction of reliable Stone Age sequences and a high-resolution chronological database. Significant questions remain regarding the technological complexity and environmental adaptations signified by the Sangoan and Lupemban, but also more fundamentally, about the precise content of these industries and their variation across time and space. At present, concepts of the Sangoan and Lupemban as early composite technologies used to hunt and gather in woodland environments are broadly supported by a range of evidence, but much work remains to be undertaken in order to demonstrate this beyond doubt. The

archaeological record on the margins of these regions, especially south-central Africa (Zambia), has provided a critical new framework for understanding these issues, but may not be representative of these industries across their entire geographic ranges. New dates from sites on the margins of Central and West Africa may yet clarify the true age and time span of these technologies, but there is a desperate need for at least one intact, datable sequence that samples the Sangoan and Lupemban from the lowland interior of Central Africa.

State of Knowledge and Current Debates

Introduction

Hunter-gatherers' study in Central Andes has been the focus of attention of Peruvian, American, and European researchers for nearly a century. Its Golden Age began in 1958 with the pioneering excavations of Peruvian archaeologists: first in Huánuco highlands, initial work led by Augusto Cardich (1958, 1964) in Uchcumachay and Lauricocha caves at high Marañón valley and then by Rogger Ravines (1965) in Perjaypata and Jatunushco caves at high Huallaga valley, and second, the research led by Ramiro Matos (1975) in Junín highlands. Simultaneously, since 1958 there was a long-term research done by the *Riva-Agüero Institute* of the *Pontifical Catholic University of Peru* (IRA-PUCP), initially led by Josefina Ramos de Cox (1969) and then by Mercedes Cárdenas (1981).

Such research was followed in the 1960s and 1970s by the work of American anthropologists in Peruvian central coast (Lanning 1963; Patterson 1966), on the coast of Casma (Malpass 1986), in the Callejón de Huaylas (Lynch 1970, 1980), and in the Ayacucho highlands (MacNeish et al. 1980, 1981). Also in the 1970s, several field projects were implemented in Junín highlands, in charge of several foreign researchers: the German Peter Kaulicke (1980, 2000), the French Danièle Lavallée and Michèle Julien, and the American Jane Wheeler (Lavallée et al. 1995), John Rick, Barbara Bocek, and Katherine Moore (Rick 1980; Rick and Moore 2000); those were promoted by R. Matos as part of the interdisciplinary and international effort of its "Punas Junín Project" of the *National University of San Marcos* (Kaulicke 2000: 307).

Besides the work led by the Swiss Fréderic-André Engel (1966) on the coast of Ancash, Lima, and Ica, deserving a special mention is his passage through the Chilca valley (southern Lima), where he conducted surveys and excavations at several sites since the mid-1960s (Engel 1988). His diggings in the emblematic La Paloma preceramic village began in 1966 and resumed in 1973 by his American collaborators including the following: Christopher Donnan in 1973–1975, John W. Greer in 1976, Terry Stocker in 1979, and Robert Benfer, Jr., in 1976–1982 and 1990, with participation of Jeffrey Quilter (burial patterns) in the 1980s, Eric White (lithics) and Joseph Vradenburg (bioanthropology) in the 1990s, the Peruvian Bernardino Ojeda in 1975–1982, and the team of *Arid Zone Research Center* of the *La Molina National Agricultural University* (CIZA-UNALM) (Benfer 2000; Engel 1988; Quilter 1989).

Terrorist violence that occurred in Peru between 1980 and 1992 made it almost impossible to develop archaeological field research, especially in the highlands. Among the few exceptions, we have the work of the Peruvian Mercedes Cárdenas (1981) in Tablada de Lurín in 1980–1988 (see also Salcedo Camacho 2014) and Santiago Uceda (1992) in the lower Casma valley in 1980–1983; the American Michael Malpass (1986) in the lower Casma valley and the Cordillera Negra of Ancash in 1980–1981;

the Croatian naturalized Peruvian Duccio Bonavia, who repeatedly visited the site of Pozo Santo, near Paracas, Ica, in 1980–1983 (Bonavia and Chauchat 1990); and the work of the American John Rick in Panaulauca in 1983–1986 (e.g., Rick and Moore 2000) and Robert Benfer, Jr., in La Paloma, southern Lima, in 1980–1982 and 1990 (Benfer 2000).

However, the 1980s saw a boom in terms of publications, mostly monographs, of the fieldwork and laboratory conducted between 1965 and 1980 (Bonavia 1982; Engel 1988; Kaulicke 1980; Lavallée et al. 1995; Lynch 1970, 1980; MacNeish et al. 1980, 1981; Malpass 1986; Quilter 1989; Rick 1980), although some original publications (e.g., Rick and Moore 2000) or translations from French and German to Spanish (Lavallée et al. 1995; Kaulicke 2000) do not saw the light until the next decade. By the mid-1990s, the fieldwork resumed, albeit limited to the central coast in Lima, basically in the Lomas de Atocongo of the lower Lurín valley (León 1999; Salcedo Camacho 2012a) and further south in the Cruz de Hueso gorge (Ugarte 2008). In parallel, the analysis of lithic material collected by Bonavia in 1977 at Tres Piedras quarry site, in lower Huarmey valley, was performed (León 2002).

In the first-half of the 2000s, several sites on the south coast were investigated during the construction of a gas pipeline, with line passing near the cities of Pisco, Chincha, Cañete, Chilca, and Lurín (Salcedo Camacho in press; see also Salcedo Camacho 2012b, 2014). In the second-half of the 2000s, research was carried out in the Orcón-Pacaybamba gorge in the middle Chancay valley, northern Lima (Goldhausen et al. 2008), as well as in the lower Río Grande valley, Nazca, Ica (Ferrando 2011). In the first-half of the 2010s, a research shortage on the central coast occurred again, being limited to the evaluation and monitoring of development projects, with results mostly remaining unpublished, but where is remarkable the discovery of a new lithic complex near the Marcona town, southern Nazca, Ica (Salcedo Camacho 2015). In addition, it should be mentioned the reassessment of the proto-Paleoindian lithic industry of the Ayacucho Complex from Pikimachay Cave, which revealed the existence of a point preform, and a pentagonal projectile point (Yataco 2013). In the second-half of the 2010s, a reanalysis of the Paleoindian lithic materials excavated by Lynch in the 1970s was performed at the National Museum of Archaeology, Anthropology and History of Peru (Ortiz 2017); and a recent research, performed at the Paleoindian site of Pampa Lechuza, Pisco valley, Ica, yielded evidences of occupation along with huge amount of lithic artifacts, including projectile points (Dulanto et al. 2018).

Geographic and Climatic Context of the Central Andes

Central Andes' physical area has been defined in very different ways, so here is a geographical and cultural criterion: the north is limited by the Santa, Tablachaca, and Pampas river basins (Ancash); the south by the imaginary line linking the towns of Marcona (Ica), Andamarca (Ayacucho), and Sondor (Apurímac); the east on the border between the mountains and the jungle; and the west by the Pacific Ocean, being framed between the following geographical coordinates: 8°12′–15°26′ Lat.S and 73°13′–78°39′ Long.W. In administrative terms, it covers the current departments of Lima, Ancash, the western part of Huánuco, Pasco and Junín, northwest Apurimac, northern and central Ayacucho, as well as Huancavelica and Ica (Fig. 1).

Such region has a large geographic and climatic diversity, and its detailed description is beyond the scope of this paper. However, generally speaking, one can say that the region is divided into mountains and coast and, in turn, is subdivided into the mountains *puna* (over 3800 masl [meters above sea level]) and intermontane valleys, while the coast is divided between the coastal valleys, the fog oasis locally known as *lomas* (below 800 masl), and the sandbanks. Basically, there are two seasons being complementary between the highlands and the coast: from November to April, wet season in the mountains is given, while on the coast, the dry season occurs; consequently, from May to October, dry season occurs in the mountains, while on the coast the wet season occurs.

Central Andes: Prehispanic Hunter-Gatherers, Fig. 1 Central Andes, Peru. Location of main sites mentioned in the text. (Adapted from *Google Earth* satellite image). Coastal sites: *1* – Casma: Sites 9, 17, 27, 29 (TPSA), Mongoncillo, El Calvario, and Cerro Negro (TAPF); *2* – Huarmey: Tres Piedras (TPSA); *3* – Huaral: Piedra Roja, Quebrada Huachoc, Quebrada Silla (TPSA), and Huaynacoto (TAPF); *4* – Chillón: Cerro de los Chivateros, Pampa de Piedras Gordas, Cerro Cruxent, Cerro Monturita, Estancia Luz (TPSA), Cerro Arenal, Pampa del Canario, and Cerro Corvina (TAPF); *5* – Lurín: Tablada de Lurín and Cerro Tres Marías (TPSA/TAPF); *6* – Punta Negra: Quebrada Cruz de Hueso 1–4 (TPSA/TAPF); *7* – Chilca: Cerro Pucusana, Chilca 1, 5, 20, 50, 304, 921, 2017, Lapa Lapa 2, La Paloma, and Cerro Calcarí 6 (TAPF); *8* – Omas (Asia): F2-E133 and F2-E136 (TAPF); *9* – Cañete: Las Gaviotas, F3-E023d (TPSA), Cerro Grande 1–4, and Hacienda La Merced 1–2 (TAPF); *10* – Pampa del Vituco 1–3 (TAPF); *11* – Paracas: Pozo Santo (TPSA), Pampas de Santo Domingo (TPSA/TAPF), Paracas 3, Visitantes and Cabezas Largas (TAPF); *12* – Nazca: La Esmeralda and Las Brujas (TAPF); *13* – Marcona: Pampa Choclón 1–2 and San Nicolás 3, 4, 6–12, 15–25, and EA-1 to 63 (TPSA); Highland sites: *14* – Callejón de Huaylas: Quishqui Puncu, Cueva del Guitarrero (TPSA/TAPF); *15* – Cordillera Negra: Tecliomachay and Huachamanmachay (TPSA); *16* – Alto Huallaga: Jatunushco and Perjaypata (TAPF); *17* – Alto Marañón: Uchcumachay 1–2 and Lauricocha 1–2 (TAPF); *18* – Junín Lake: Pachamachay (TPSA/TAPF); *19* – Puna of Junín: Telarmachay (TPSA/TAPF), Acomachay, Cuchimachay, Panaulauca, and Uchkumachay-Tilarnioc (TAPF); *20* – Alto Chilca: Quiqché and Tres Ventanas 1–2 (TAPF); and *21* – Ayacucho: Jaywamachay, Pikimachay (TPSA/TAPF), Ayamachay, Rosamachay, and Puente (TAPF)

The puna has the most rigorous and seasonal climate, with dry air and daily temperature ranging up to 50 °C, with an average annual rainfall of 60–100 cm, which limits the growth of trees and shrubs, such as molle and other plants (genera *Inga*, *Schinus*, *Polylepis*), and simultaneously it supports steppe vegetation of grasses such as ichu (genera *Poa*, *Festuca*, *Eragrostis*, *Calamagrostis*, and *Stipa*) on which some padded cactus (genus *Opuntia*) spread (Lynch 1980]). In the open puna growing tubers, bulbs, and roots, vegetables such as potatoes (*Ullucus tuberosus*), oca (*Oxalis tuberosa*), olluco (*Ollucus tuberosus*), lupine or tarwi (*Lupinus mutabilis*), and quinoa (*Chenopodium quinoa*) grow, while in humid areas, wetland vegetation known as bofedales

grows, and on the lakeshores the cane fields (bofedales) of rushes (juncos) and cattails (totoras) grow (Lavallée et al. 1995; Lynch 1980).

Likewise, the valleys show a stratified ecology depending on the altitude and the differential distribution of rainfall, and its seasonality is pronounced for its dry condition, being less productive annually, particularly in their lower parts, where the vegetation is very productive but dispersed; the lack of permanent pasture causes a low density in greater fauna with respect to the puna (Rick 1988). Meanwhile, in few coastal valleys that have permanent rivers and, although the variation in annual temperature allows a double harvest, seasonal fluctuation in river flow causes only a fraction of the land that can be irrigated for a second crop; moreover, the lomas vegetation is mostly herbaceous, heavily dependent on weather and other environmental conditions to produce considerable amounts of food (Cohen 1978).

Among the fauna, we can consider basically mammals, following in importance birds, fish, and amphibians. Undoubtedly, the most important mammals are larger ungulates such as deer, including the Andean deer (known as taruca or huemul) inhabiting the highlands, and white-tailed deer (*Odocoileus virginianus peruvianus*) living in the intermontane valleys and on grounds below the highlands and visiting the coastal lomas; in addition, there are South American camelids, including two wild species, vicuña (*Vicugna vicugna*) inhabiting the highlands and guanaco (*Lama guanicoe*) which are distributed across the highlands, the valleys, and the coastal lomas, and two domestic species, alpaca (*Lama pacos*) which lives on 4000 masl and feeds bogs and llama (*Lama glama*) which inhabits grasslands on 3000 masl (Lavallée et al. 1995; Wheeler 2000).

There are also medium-sized mammals, basically carnivores of two families: the canids are represented by Andean fox (*Dusicyon culpaeus andinus*), skunk or zorrino (*Conepatus rex rex*), and domestic dog (*Canis familiaris*), while the felids include cougar or puma (*Puma concolor*) and two species of wild cat (*Felis colocolo* and *F. jacobita*) (Lavallée et al. 1995). Additionally, there is a mustelid carnivore, common opossum or zarigüeya, who lives around the 3500 masl (Lynch 1980; Rick 1980). Also, small mammals include several species of rodents, with wild guinea pig or cuy silvestre (*Cavia aperea*) and northern viscacha or vizcacha (*Lagidium peruanun inca*) that lives between 3000 and 5000 masl being remarkable (Lavallée et al. 1995; Lynch 1980).

Although in open puna birds scarce, they abound in the valleys. Typical highland birds include two species of partridge (*Nothoprocta ornata* and *Tinamotis pentlandi*) and a bird of prey: American vulture or condor (*Vultur gryphus*). Additionally, the puna includes birds such as duck, goose, ibex, heron, flamingo, etc., while the intermontane valleys have huacha, duck, coot, and parihuana (Lavallée et al. 1995; Lynch 1980). Among the fish are small species that inhabit the lakes or streams, such as gudgeon and catfish (genera *Orestias* and *Pygidium*), while among the amphibians stands the Junín's giant frog (*Batrachophrynus macrostomus*), which inhabits the streams and lagoons (Lavallée et al. 1995; Rick 1980).

Hunter-Gatherer Settlement Systems

For decades, researchers tried to understand how populations of hunter-gatherers adapted to their environment, managing scarcity or dispersion of natural resources; the temporal abyss that separates us from those preliterate populations largely exceeds the collective memory, which hinders any attempt to reconstruct the history of human groups settled in a region where the landscape and climate varied throughout the year, causing the resources to be relatively abundant in part of the year and scarce in the other; so, there were no ideal places to settle, nothing like an "Andean Eden"; therefore people should move from one place to another within its territory, sometimes the whole group, but often split into subgroups (Salcedo Camacho 2012b: xiii). Unfortunately, the study of past societies cannot be done directly, as artifacts, bones, and hearths do not speak for themselves, nor its distribution produces anthropological information per se if we disregard ethnographic comparison, although the application of actualism can also lead to erroneous conclusions, because modern behavioral patterns do not necessarily fit with the old ones (Salcedo Camacho 2012b: xvi).

Binford (1980) proposed two opposite and complementary categories of mobility for hunter-gatherers: (a) *residential mobility* (displacement of the entire group from one camp to another) and (b) *logistic mobility* (movements in search of food or raw material made by individuals or small groups who return to the same base camp); both types of mobility are related to a couple of strategies:

Foragers produce residential camps and locations, making frequent residential movements and short logistic movements to bring resources from locations to camp; archaeologically, their activities are barely visible as resources are little processed at locations, nor store them in the camps, leaving its remains scattered in the landscape more than focused on recognizable sites.

Collectors produce base camps, logistical camps, locations, stations, and deposits, making infrequent residential movements toward key locations and long logistic movements to bring resources to the base camp and store food; archaeologically, its activities are highly visible because of processing resources, while the size and density of their sites vary according to the season they are used.

The adaptation of the Binford's model to the Andean case was applied in specific regions, such as the coastal hills of the valleys of the Chillón (Lanning 1963; Patterson 1966) and Lurín (Salcedo Camacho 2012a), in Lima; the intermontane valley of Callejón de Huaylas, in Ancash (Lynch 1967, 1980); and the puna of Junín (Lavallée et al. 1995; Wheeler 2000). However, it was Salcedo Camacho (2012b, 2014) who since 1997 widely applied the model to the Central Andes, linking the regions of puna and intermontane valleys, with the regions of coastal valleys and lomas establishing interactions between different cultural complexes.

Updated Chronological Frame

Central Andes were not inhabited exclusively by a single cultural complex but by several complexes belonging to two different traditions (Salcedo Camacho 2014). In such cultural context, the use of a new chronology based on calibrated radiocarbon dates was required, taking as reference the new *carbon isotope stages* (climatic stages deduced from cyclical variation in the atmospheric carbon-14 recognizable in the calibration curves and where deep valleys and plateaus correspond to times of dimmed solar activity, known as the *Great Solar Minima*, which in turn would have influenced the development patterns of past societies) (Salcedo Camacho 2011).

All radiocarbon dates mentioned in the text, as well as in Table 1, were calibrated using the OxCal v.3.10r program, developed at *Oxford Radiocarbon Accelerator Unit* by C. Bronk Ramsey (2005) (available at https://c14.arch.ox.ac.uk/embed.php?File=oxcal.html), which was updated to use the IntCal13 calibration curve (Reimer et al. 2013); the program was configured to use two standard deviations (95.4%) and 100 k MCMC iterations, using dates included in the references cited in this text and those included in Salcedo Camacho (2014).

During the Holocene, human populations adapt to a more benign, less frigid climate, where the increase in global temperature led to the domestication of plants and animals (Salcedo Camacho 2012b). In cultural terms, this climate period can be divided up into five cultural stages grouped in two epochs (Salcedo Camacho 2012b, 2014):

Protoarchaic epoch (13,400–7400 years Cal. BC), which corresponds to the initial stage of settlement and dissemination of human populations across the Americas and transition between the Late Pleistocene and Early Holocene. It is subdivided into two cultural stages: (a) *Early Protoarchaic* (13,400–11,000 years Cal. BC), which corresponds coarsely to climate setback known as the *Younger Dryas*, and (b) *Late Protoarchaic* (11,000–7,400 years Cal. BC), which corresponds to the Preboreal.

Archaic epoch (7400–1700 years Cal. BC), which corresponds to the development and regionalization of cultures without pottery, the processes of sedentarism and domestication of plants and animals, and the beginning of use of marine resources. It is subdivided into three cultural stages:

Central Andes: Prehispanic Hunter-Gatherers, Table 1 Inventory of radiocarbon dates published for central Andean complexes belonging to the *South American Paleoindian Tradition* (TPSA) and the *Andean Foliated Point Tradition* (TAPF), calibrated with OxCal v.3.10r program using the IntCal13 calibration curve (Reimer et al. 2013), except where is indicated with an asterisk (*), corresponding to IntCal09 calibration curve (Reimer et al. 2009). (Modified after Salcedo Camacho 2014: 336–337, 441–443, and 448). Calibrated dates are expressed in "years Cal. BC," except where indicated with "AD" (*Anno Domini*). Laboratory codes marked with an asterisk are considered inconsistent with site's stratigraphy

(a) *Early Archaic* (7400–5900 years Cal. BC) coincides with the proliferation of cervids and camelids after the extinction of Pleistocene megafauna, causing a radical change in diet and resource utilization strategies, resulting in a generalized and indiscriminate hunting of animals.
(b) *Middle Archaic* (5900–2800 years Cal. BC) is the time when hunters learn the behavior and distribution of new species, using a more profitable and rational selective hunting strategy and improving their lithic technology (changes in the shape and relative frequency of certain types of artifacts, making them increasingly efficient), which in turn leads to the implementation of a control strategy and management of semi-domesticated camelids in the highlands; in parallel, other groups experimented with the domestication of plants in the intermontane and coastal valleys, used the resources obtained in the lomas, and set in the first villages of fishermen and horticulturists in a littoral zone.
(c) *Late Archaic* (2800–1700 years Cal. BC), in the highlands, is the time when control over camelids evolves from a simple intervention in breeding herds to the implementation and dissemination of pastoralism; in parallel, in the valleys the domestication of several plant species, which begin to be brought to the coast, occurs, while in the villages of fishermen and horticulturists, the basis of what later became known as agriculture develops.

Early Cultural Traditions

All preceramic sites in Central Andes can be sorted in two of the five early cultural traditions of South America, namely, the *South American Paleoindian Tradition* ("TPSA" in Spanish) and the *Andean Foliated Point Tradition* ("TAPF" in Spanish) (Salcedo Camacho 2014).

TPSA populations are highly adaptable at both biological and cultural levels, being organized in small family groups (micro-bands) which split or merge depending on the environmental conditions, using their artifactual diversity to tame the variety of ecosystems they colonized; as example, their spear points were originally used to hunt Pleistocene mega-mammals, but then were used as harpoons for fishing or as knives to process minor prey's carcasses during Early and Middle Holocene; their stone tools include bifacial preforms, lanceolate points, plain-convex scrapers (*limaces*), choppers, and other coarse unifacial artifacts (Salcedo Camacho 2014: 201). TPSA cultural complexes in Central Andes are the following (Salcedo Camacho 2014: 279–299):

Paiján Complex (formerly "Chivateros Complex" on the central coast) (11,000–5100 years Cal. BC): Sites 9, 17, 27, and 29 (Uceda 1992) (Casma, Ancash); Tres Piedras PV35-3 (León 2002) (Huarmey, Ancash); Piedra Roja PV44-Q/01, Quebrada Huachoc PV44-H/01, and Quebrada Silla PV44P/39 (Goldhausen et al. 2008); Cerro de los Chivateros PV46-27, Pampa de Piedras Gordas PV45-28 and 29B, Cerro Cruxent PV45-45, 48, 49, 50, and 51, Cerro Monturita PV45-66, 67, and 70, and Estancia Luz PV45-72, 83, 84, and 85 (Lanning 1963; Patterson 1966; cf. Bonavia 1982) (northern Lima); and early occupations at Tablada de Lurín (Cárdenas 1981; León 1999; Ramos de Cox 1969) and Cerro Tres Marías (Cárdenas 1981) and Quebrada Cruz de Hueso 1–2 (Ugarte 2008) (southern Lima)

Santo Domingo Complex (8100–7400 years Cal. BC): Las Gaviotas and Evidence F3-E023d at Cerro Grande (Salcedo Camacho 2014, in press) (Cañete, Lima); Pozo Santo (Bonavia and Chauchat 1990), Paracas 14a VI-3, Visitantes 14a VI-96, and Pampas de Santo Domingo 14a VI-514 (Engel 1966) (Paracas, Ica); and San Nicolás SN3-4, 6-12, 15-25, EA-1 to 63 and Pampa Choclón PC1-2 (Salcedo Camacho 2015) (Marcona, Ica)

Huaylas Complex (11,000–9000 years Cal. BC): Quishqui Puncu (Lynch 1967), Cueva del Guitarrero (disturbed Levels III–IV) (Lynch 1980), and Tecliomachay and Huachamanmachay (Malpass 1986) (Ancash)

Junín Complex (9000–7400 years Cal. BC): Pachamachay (Levels 31–32) (Rick 1980) and Telarmachay (Level VIIb) (Lavallée et al. 1995) (Junín)

Mantaro Complex (11,000–8100 years Cal. BC): Jaywamachay (Levels J and G) (MacNeish et al. 1980, 1981) (Ayacucho)

Ayacucho Complex (16,300–13,400 years Cal. BC): Pikimachay Ac 100 (Levels h, h1, and h2) (MacNeish et al. 1980, 1981; Yataco 2013) (Ayacucho)

Otherwise, the TAPF presents a pan-Andean distribution, although their sites are more frequent in the central highlands of Peru and semiarid northern Chile; it emerges as a tradition of hunter-gatherers fully nomadic adapted to the highlands, the intermontane and coastal valleys, and the lomas; but then they turn into a gradual sedentarism, leaving their generalized strategies by another, more selective ones, with the subsequent domestication of plants (especially squash and beans) and animals (camelids, guinea pig), with the consequent adoption of pastoralism and incipient horticulture; their stone tools are characterized by the widespread presence of small willow leaf ("foliated") points along the entire sequence, along with a handful of *fossil index* artifacts (very diagnostic, but scarce items of brief permanence in the archaeological record) that change from one period to another (e.g., points with ailerons and eventually serrated margins in early phases were replaced by geometric shapes, first triangular and then rhomboidal in later phases), facilitating their chronological ordering (Salcedo Camacho 2012b, 2014: 367, 370, 372–393).

It should be noted the Chilca Complex sites produced the first semisedentary settlements in the region, consisting of semicircular dwelling structures held by poles, and covered by vegetable fibers or possibly animal leather, defining living spaces with diaphanous activity areas (cooking, burial, etc.), while its lithic industry is characterized by elongated leaf points and the necessary equipment for fishing and harvesting of marine resources (such as shell hooks, harpoon barbs, plus strings, and textiles elaborated on vegetable fiber); finally, the dead were carefully buried in mats, inside or near their huts (which were abandoned and demolished after the funeral), accompanying them with various offerings (Salcedo Camacho 2014: 423–427). TAPF cultural complexes in Central Andes are the following (Salcedo Camacho 2014: 372–393, 423–427):

Mongoncillo Complex (5100–4600 years Cal. BC): Mongoncillo 1251 IV-15S-1b, El Calvario PV32-1, and Cerro Negro PV32-2 (Malpass 1986) (Casma, Ancash)

Lauricocha Complex (10,500–1700 years Cal. BC): *On the coast:* Huaynacoto PV44-P/20 (Goldhausen et al. 2008), Cerro Arenal PV45-71 and 72A, Pampa del Canario PV45-31–35, 37–39, 58, and 89–93, and Cerro Corvina PV45-20, 30, and 65 (Lanning 1963; Patterson 1966) (northern Lima); Tablada de Lurín (Cárdenas 1981; León 1999; Ramos de Cox 1969), Cerro Tres Marías (Cárdenas 1981; Salcedo Camacho 2012a), Evidences F2-E133a,b and F2-E136a,b (Asia); and Cerro Grande 1–4, Hacienda La Merced 1–2, and Pampa del Vituco 1–3 (Salcedo Camacho 2012b, 2014, in press) (southern Lima). *On the intermontane valleys:* Quishqui Puncu (Lynch 1970), Cueva del Guitarrero PAn 14–102 (Complex II), and Callejón de Huaylas PAn 8–126, 12–51, 12–53, 12–57, and 12–58 (Lynch 1980) (Ancash); Jatunushco and Perjaypata (Ravines 1965) (Huánuco); and Ayamachay Ac 102 (Stratum VII), Jaywamachay Ac 335 (Strata J–C), Pikimachay Ac 100 (Levels h–f), Rosamachay Ac 117 (Level D), and Puente Ac 158 (Levels XIIA–IC) (MacNeish et al. 1980, 1981) (Ayacucho). *On the highlands:* Uchcumachay 1–2 and Lauricocha 1–2 (Phases I–III) (Cardich 1958, 1964) (Huánuco); Quiqché and Tres Ventanas 1–2 (Engel 1988) (Lima); and Pachamachay (Phases II–IV) (Rick 1980), Acomachay, Cuchimachay, Telarmachay (Phases VIIa–IV) (Lavallée et al. 1995; Wheeler 2000), Panaulauca (Rick and Moore 2000), and Uchkumachay-Tilarnioc (Strata 4–6) (Kaulicke 1980, 2000) (Junín)

La Esmeralda Complex (4600–2800 years Cal. BC): La Esmeralda CAH 88 (Isla 1990) and Las Brujas (Ferrando 2011) (Nazca–Ica)

Chilca Complex (9900–1700 years Cal. BC): Quebrada Cruz de Hueso 3–4 (Salcedo Camacho in press), Cerro Pucusana 12B-VII-908, Chilca 1 12B-VII-1, Chilca 20 12B-VII-20,

Lapa Lapa 2 12B-VII-93, La Paloma 12B-VII-613 (Benfer 2000; Engel 1988; Quilter 1989), and Cerro Calcarí 6 (Salcedo Camacho 2012b, 2014, in press) (Chilca, Lima) and Cabezas Largas 14A-VI-I and Pampas de Santo Domingo 14A-VI-514 (Engel 1966) (Paracas, Ica)

Classical Research

Here, the better known research are briefly explored, organized according to both cultural traditions previously mentioned (TPSA and TAPF), and listed from north to south, starting from the coast and continuing through the highland.

For TPSA in Central Andes, the coastal sites are distributed between two complexes. First, the widely distributed Paiján Complex, which in the Casma valley (Ancash) includes six sites: 1251 IV-8V-1, a small basalt workshop (250 m^2), where two Chivateros-type preforms and numerous flakes were found; and Campanario 1252 III-27M-2b, which includes a fairly large area (4800 m^2), divided into three units that were used as workshops for white sandstone, finding numerous Chivateros-type preforms, plus bifacial pieces in retouching process for obtaining Paiján-type spear points (Malpass 1986); there are also Sites 9, 27, 29, and specially Site 17, Unit 2, where an area of 60 m^2 was excavated finding a lot of unifacial artifacts (retouched flakes, knives, and denticulates) associated with Paiján-type points (Uceda 1992). In the Chillón valley (northern Lima), there are two major sites: Cerro de los Chivateros PV46-27, a quarry located on the north bank of the river basin, where two strata with numerous bifacial blanks and Chivateros-type preforms were found (Lanning 1963; Patterson 1966), an occupation that was dated in 10,750–9800 years Cal. BC; also at Estancia Luz PV45-84, a small excavation was conducted, finding some food remains, besides lithic artifacts, including two lanceolate points (Lanning 1963), an occupation that was dated in 6450–5280 years Cal. BC. Second, for Santo Domingo Complex, there is Pozo Santo 14b IV-45, not far from the Paracas Bay (northern Ica), a quarry which produced several Chivateros-type preforms at different stages of reduction, although neither associated points were found nor datable organic material (Bonavia and Chauchat 1990); also, there are excavations in the open-air sites of Paracas 14a VI-3, Visitantes 14a VI-96, and Pampa de Santo Domingo 14a VI-514, where various lanceolate points were recorded (Engel 1966), one of these occupations being dated in 8450–7500 years Cal. BC.

Meanwhile, highland sites of this tradition are divided into three originally unnamed complexes, recently named by Salcedo Camacho (2014: 294–297). First, Huaylas Complex consists of a handful of settlements in the Cordillera Negra (Ancash) including Quishqui Puncu (3040 masl) open-air site, excavated by 2 × 2 m units until covering 370 m^2, and recovering two fragments of Fishtail-type point from the Unit L and several basal fragments of lanceolate points from other units (Lynch 1970); Cueva del Guitarrero (2580 masl) shows a partially disturbed stratigraphy (Lynch 1980); Huachanmanmachay (4500 masl) and Tecliomachay (4500 masl) caves are characterized by the presence of stemmed points of triangular blade and rough manufacture, along with several utilized flakes, notches, burins, and so on (Malpass 1986). Second, the Junín Complex includes Pachamachay Cave (near San Blas, Junín), Phase I, which produced some triangular projectile points with slightly concave base (Rick 1980), associated to a date of 9400–7500 years Cal. BC, while Telarmachay rock-shelter (near San Pedro de Cajas, Junín), Level VIIb, produced few artifacts, standing out a pentagonal projectile point with notched base (Lavallée et al. 1995), associated with a date of 8250–7650 years Cal. BC. Third, the Mantaro Complex is represented by the Jaywamachay Ac 335 cave (Ayacucho valley, a tributary of the Upper Mantaro River, Ayacucho), whose Levels J3 and J2 produced three incomplete obsidian points (which seem to correspond to the Lake Madden [Panama] and Fishtail types), as well as a pentagonal point made of basalt from Level G (MacNeish et al. 1980, 1981), dated in 10,700–8500 years Cal. BC.

For TAPF in Central Andes, sites are divided into four complexes, three of them purely coastal,

while the latter is both highland and coastal one (from the puna to the lomas). First, the Mongoncillo Complex consists of 38 sites (including Mongoncillo 1251 IV-15S-1b) arranged on a long knoll in the Casma coast (Ancash), where the existence of foliated points was reported (Malpass 1986); additionally, there are El Calvario PV32-1 and Cerro Negro PV32-2 sites, dated in 5210–4790 years Cal. BC (see Salcedo Camacho 2014). Second, La Esmeralda Complex is represented by La Esmeralda CAH 88 site, which produced domestic contexts of two superimposed structures formed by walls of *quincha* (canes covered with mud mortar), and in one of them, there was the burial of an adult woman associated to shell (*Argopecten purpuratus*) offerings, basketry, and some lithic artifacts, including three foliated points (Isla 1990). Eight dates obtained correspond to 4550–3600 years Cal. BC.

Third, Chilca Complex is composed of several settlements recorded along the coast and the lomas south of Lima, including two sites in the lower Chilca valley: La Paloma site (12B-VII-613) is arranged on the homonymous loma and consists of a series of mounds and household waste midden covering, 15 ha; excavations revealed more than 40 semicircular dwelling structures – raised with willow posts (*Salix* sp.), tied with vegetable fibers, and covered by herbs – within which there were 251 human burials associated to foliated projectile points, fishing artifacts (shell and cactus spine harpoons, nets, ropes, lithic counterweights, buoys made from pumpkins, etc.), diverse baskets, as well reed (*Cyperus* sp.) and totora (*Typha angustifolia*) mats (Benfer 2000; Quilter 1989). Twenty dates obtained span 7050–2100 years Cal. BC. Also, Chilca 1 (12B-VII-1) site covers about 2 ha, showing an unbroken succession of 16 cultural layers (1,5 m deep), with the presence of semicircular dwelling structures associated with human burials, domestic refuse of both marine and lomas origins, incipient agriculture products such as beans (*Phaseolus vulgaris*), numerous artifacts both lithic and vegetable fiber (basketry, cordage, and mats), bone tools, etc. (Engel 1988). Ten dates from East Sector span 4950–2650 years Cal. BC.

Fourth, Lauricocha Complex comprises sites of different types located from the highlands to the lomas, related to the process of domestication of plants and animals, with a lithic technology that is distinguished by small foliated points, accompanied by cores, flakes and various artifacts on flake, as well as occasional grinding tools and the development of the rock art (anthropomorphic and animal figures) and individual burials in shallow graves; 124 dates of this complex span 10,500–1700 years Cal. BC (Salcedo Camacho 2012b, 2014). Among the most important sites can be mentioned two highland sites:

Telarmachay rock-shelter (4420 masl), near San Pedro de Cajas (Junín), is the preceramic locality most systematically excavated in Central Andes; French Archaeological Mission – led by Danièle Lavallée – began explorations at the site in 1974 with a small 0.6 × 0.5 m test pit, revealing the existence of at least five stratigraphic units; then, between 1975 and 1980, an area of 35 m^2 was excavated showing eight cultural layers, of which the lower five were preceramic, where a large amount of food waste was found, basically skeletal remains of cervids and camelids associated to lithic artifacts (Lavallée et al. 1995). Shelter occupation was intensifying over time increasing the usable area: presence of traces of postholes surrounded by rocks advancing down the slope along the phases of occupation; in addition, the hearths are in marginal positions within the sheltered area, perhaps to avoid the smoke concentrating on the center of the rock-shelter; hide processing evidence was also found, as well as maintenance activities (food preparation, tool manufacture, etc.) (Lavallée et al. 1995).

Pachamachay Cave (4300 masl), near San Blas (Junín), was first excavated by Ramiro Matos in 1969–1970 by a 12 × 1 m trench arranged on the slope of the cave, recognizing 16 strata (3–13 were preceramic) containing lithic artifacts and great amount of bones (Matos 1975); diggings extended in 1973 by the German Peter Kaulicke, finding evidence of hearths, workshops, etc. (Kaulicke 2000). Later excavations were performed by American John Rick in 1974–1975, consisting in two areas of 3 × 3 m and 1 × 1 m, respectively (10 m^2), identifying

33 and 27 layers, respectively; from the resulting 7 phases, the first 5 were preceramic (Rick 1980).

Lauricocha Complex was redefined in terms of calibrated radiocarbon chronology, the identification of four fossil index foliated points (with ailerons, triangular, or rhomboidal), and the definition of cultural traits for each stage (from Salcedo Camacho 2012b, 2014: 379):

Proto-Lauricocha Phase (10,500–7400 years Cal. BC): Presence of foliated points with small ailerons located in the lower third of the piece, setting a pseudo-peduncle; in the highlands low-density settlements in caves and rock-shelters appear, with evidence of little selective hunting of Holocene fauna (e.g., guanacos, white-tailed deer, and taruca or huemul), while in the coast small subgroups of hunters will eventually visit the lomas in search of preys (guanacos and white-tailed deer).

Lauricocha I Phase (7400–5900 years Cal. BC): Presents points with ailerons located in the middle third of the piece, with straight-converging sides apex, possibly serrated and pseudo-peduncle; in the highlands, the rational exploitation of the Holocene fauna (guanacos and white-tailed deer) is given, while on the coast, hunter subgroups visit more frequently the coastal valleys and lomas.

Lauricocha II Phase (5900–2800 years Cal. BC): Includes triangular points ranging from equilateral to isosceles, with straight-converging sides or amygdaloidal contour; domestication of South American camelids begins in the highlands, as well as experimenting with crops, both in the intermontane and the coastal valleys, where more stable base camps appear in the middle valleys, while during the coastal wet season, there is a regular use of the lower valleys and lomas, as well as the sandy beaches, with the consequent consumption of a limited variety of shellfish.

Lauricocha III Phase (2800–1700 years Cal. BC): Consists of short or elongated rhomboidal points, with straight or slightly convex sides and slightly rounded base; in the highlands, the domestication of camelids is well advanced, and there is an incipient horticulture, while on the coast, retreat of the Lauricocha Complex groups occurs (showing an abrupt drop in the consumption of marine mollusks), being displaced by the semisedentary Chilca Complex populations who settled on the littoral and presumably control access to seashore.

In sum, the hunter-gatherers of the Lauricocha Complex practiced the Binford's collectors strategy, performing rotating movements between base camps located in the higher puna and logistics camps set in the lower puna and high valleys, while other groups established their base camps in the intermontane and coastal valleys, maintaining logistical camps in the lower valleys, with the consequent exploitation of lomas resources by the coastal groups (Salcedo Camacho 2012b). This coastal Lauricochean strategy was followed by his peers of Mongoncillo and La Esmeralda Complexes; and, on the other hand, the semisedentary populations of the Chilca Complex practiced the Binford's foragers' strategy, settling at the foot of the lomas, mostly exploiting marine resources, supplemented with some lomas resources.

Recent Research

In this section, the most recent works of the last two decades are exposed, and, usually, those do not appear are cited in the synthesis; this is partly due to the fact that such publications were made by young researchers and partly because the elapsed time has not allowed its widespread dissemination in academic circles, but also because at that time there were few events where information about Central Andes hunter-gatherers could be exchanged. All authors mentioned in this section are Peruvian, except where otherwise indicated.

Tablada de Lurín and Cerro Tres Marías

Tablada de Lurín is a plain within the Lomas de Atocongo, between Villa Maria del Triunfo and Villa El Salvador, south-central Lima (Salcedo Camacho 2012a). Previous research in the area between 1958 and 1988 by Josefina Ramos de Cox and Mercedes Cárdenas of the Riva-Agüero

Institute (IRA-PUCP) reported three open-air sites with preceramic evidence, including both Paleoindian and foliated projectile points (Cardenas 1981; Ramos Cox 1969).

First site (originally "Area A" or "First Area") is located at an elevation that dominates the center of the plain (290 masl; 12°11,2′ Lat.S; 76°54,9′ Long.W) and yielded lithic material with bifacial knapping of Chivateros type, along with the burial of a 10-year-old individual covered with red ocher, being dated in 9200–7700 years Cal. BC (GaK-1599); a sample from the shell midden of Sector 1 (Area 3) was dated in 6000–5670 years Cal. BC (PUCP-14), likewise, a sample of unknown exact origin, was dated in 5650–5050 years Cal. BC (GaK-1859), while the Grave 1 (Area 20), including a headless corpse associated to a puma or cougar jaw (*Felis concolor*), was dated in 2500–1900 years Cal. BC (GaK-2353) (Cárdenas 1981; see also Salcedo Camacho 2012a, 2014).

Since late 1991, work on this site (renamed "Sector SE-A") was led by Polish archaeologist-naturalized Peruvian Krzysztof Makowski (PUCP), who in 1993 assigned Elmo León to conduct a thorough analysis of the lithic material recovered until 1994 (Salcedo Camacho 2012a), revealing two lines of the *chaîne opératoire* (operational chain of technical processes involved in step-by-step production, use, and disposal of artifacts), based in andesite-sandstone and chalcedony, although other possible lines include pebbles and silicified hematite (León 1999). In parallel, Makowski commissioned the excavation six 5 × 5 m units (150 m^2) in a dense area within the Archaic occupation, which by then was estimated to cover at least 1,5 ha (15,000 m^2) (Salcedo Camacho 2014). Initial three units were excavated by Hernán Carrillo in 1994–1995 and 1998, while the fourth was excavated by Elmo León in 1994, being the last two excavated by Polish Karol Karasiewicz and Katarzyna Barska-Piotrowska between 1995 and 1996 (Salcedo Camacho 2012a, b, 2014).

The interpretation of site stratigraphy is problematic due to soil formation processes in lomas and numerous intrusions caused by burials of the first millennium AD, but mostly because of the diversity of criteria used in its denomination (Salcedo Camacho 2014). Ramos de Cox's lower occupations (Makowski's Layer E) turned out to be "ghosts" caused by vertical migration of archaeological material (from overlying Makowski's Layer D) through the numerous desiccation cracks crossing the strata (Salcedo Camacho 2012a, 2014). Layer D is a humic horizon of more than 1 m thick developed in the presence of lomas vegetation, which presents a number of overlapping ephemeral occupations, with activity areas (mollusk shell removal, consumption, or lithic reduction) structured around combustion areas (Makowski 1996 [cited in Salcedo Camacho 2012a: 35, 2014: 387]).

Second site (originally "Area B1," now "Cerro Tres Marías" [CTM]) is located at the foot of Las Tres Marias hill (310 masl; 12°11,0′ Lat.S; 76°55,2′ Long.W), where Ramos de Cox commissioned Jaime Deza the excavation of two 10 × 10 m units (200 m^2) in 1976–1977, recovering a lanceolate stemmed spear point of Luz type, associated with lithic *débitage* (waste by-products resulting from stone tool manufacture), hearths, and shell middens (Cardenas 1981); associated organic remains were dated in 9250–8600 years Cal. BC (PUCP-101) (Salcedo Camacho 2012b, 2014).

In 1995, following Deza's visit to Makowski's project, the latter commissioned Giancarlo Marcone digging a segmented trench of 50 m^2 ("Sector NW-E"), located to the east of Deza's area, which turned out to be sterile, so Makowski decided to intervene a new area ("Sector NW-D") located closer and north of the original excavation of Deza and where Carrillo made a surface collection; finally, the excavation was commissioned to Luis Salcedo, using as a guide a profile exposed by heavy machinery work done months ago by the mayor authority (Salcedo Camacho 2012a, b, 2014).

Between December 1995 and April 1996, the excavation of Salcedo covered 23 m^2 of approximately 40 m^2 remaining site, revealing a sequence of 3 archaic phases embedded in a practically unaltered sediment matrix (due to better geomorphological conditions than those observed in the plain), making a total of nine ephemeral

occupations (Fig. 2a), a sort of logistic camps, with the presence of various activity areas: lithic reduction and processing and discard of bones and mollusk shell remains, associated to combustion areas (well-defined hearths, but without stone structure) and dwelling areas (in Phase 3) constituted by small, semicircular compartments or "windbreaks" of very short use, made with small accumulation of common stones forming arcs, with equidistant gaps for the location of thin posts; within them or in direct association, some lithic artifacts were found: foliated points (Fig. 2b), plain cores, endscrapers, a sidescraper, and modified flakes, along with a significant amount of food waste (Salcedo Camacho 2012a).

Lithic material recovered in this site consists of 1432 items, of which 1420 (99.16%) are chipped, belonging mostly to *débitage* (by-products of the knapping process) (1380; 96.37%) and being segregated in cores (9; 0.63%), unmodified flakes (86; 6.01%), and core or flake fragments (*cassons*/*debris*, respectively) (1285; 89.73%), while only 40 (2.79%) are tools (6 point preforms, 4 projectile points, 5 endscrapers, 2 knives, 1 sidescraper, 16 modified flakes, and 6 *cassons*/*debris* retouched a posteriori); it also has 12 (0.84%) non-chipped items, including hammerstones (11; 0.77%), and grinding stone (1; 0.07%) (Salcedo Camacho 2012a: 223–224, Appendix C).

It was possible to determine five lines of the *chaîne opératoire*: volcanic, meta-volcanic (andesitic tuffs and meta-andesites), silicified hematite, and to a lesser frequency sandstone and quartz. From rock types used for making artifacts, it becomes clear that raw material procurement radius is limited to the area of Tablada de Lurín, ruling out the possibility for long-distance transport, with the exception of a projectile point made of jasper, probably from the central highlands (Salcedo Camacho 2012a: Appendix D).

Among the organic remains exist macrobotanical remains and pollen samples that determine the presence of Cactaceae (cacti), Poaceae (grasses), and Solanaceae, among others (Salcedo Camacho 2012a: Appendices B and G). The 2528 malacological remains correspond to a minimum number of individuals equal to 1379, of which 1349 are the bivalve known as macha (*Mesodesma donacium*), with only 16 individuals of different species of clams and mussels, along with just 14 gastropods known as chanque (*Concholepas concholepas*) and little plates of a polyplacophoran known as chitón (Salcedo Camacho 2012a: 357, 362, Appendix F). Alto exist 2093 bone fragments of animals, including camelids like guanaco (*Lama guanicoe*), along with cervids like white-tailed deer (*Odocoileus virginianus*), plus some remains of lomas rodents and birds mostly charred, as well as both river and sea fish remains (Salcedo Camacho 2012a: 311, Appendix E).

Finally, a third site was accidentally discovered in the early 1970s, during works with heavy machinery, where Gonzáles del Río exposed an occupation that includes a burial of a dolichocephalic individual partially cremated (Burial 214), dated in 7250–6350 years Cal. BC (GaK-2470) (Salcedo Camacho 2014).

Quebrada Cruz de Hueso 1–4

Between 1996 and 2001, work was carried out in two open-air sites of the Quebrada Cruz de Hueso (440 masl; 12°19,7′ Lat.S; 76°40,1′ Long.W), located on an alluvial terrace at the foot of the Vigía hill, north of Lomas de Caringa, in Pampas de San Bartolo, Punta Negra (Lima, Lima). Both components are separated 0.5 km: a workshop of 500 m^2 (with lithic material and some mollusk shells) and a camp of about 1000 m^2 (a shell midden associated to grinding artifacts) (Ugarte 2008: 39, 41, 44). The workshop (Site 1) has four lithic concentrations (A: 23 × 7 m, B: 9 × 6 m, C: 7 × 6 m, and D: small, no data), being white quartz the predominant raw material, although in Concentration C brown quartz preforms were recorded. This area was divided into 500 units of 1 m^2, with 29 being collected and 43 excavated to 10 cm depth (Ugarte 2008: 44–46). Moreover, in the camp (Site 2), four 1 m^2 units (4 m^2 in total) were excavated, reaching only 12 cm deep due to the presence of a caliche level (Ugarte 2008: 47).

In total, lithic material recovered in the site includes 19,584 chipped items, belonging mostly to *débitage* (19,548; 99.82%), being sorted in cores (10; 0.05%), flakes (1425; 7.28%),

Central Andes: Prehispanic Hunter-Gatherers, Fig. 2 Cerro Tres Marías (CTM) open-air site. Field record and lithic artifacts. (**a**) Plan of the occupation surface of Subphase 3A (Layer D, Levels 7, 8, and 9[1]), at the beginning of Late Archaic: *1* – Spatial distribution of lithic and organic remains regarding the windbreaks (Modified after Salcedo Camacho 2012a: Fig. 75); *2* – Record of improvised structures H3A-1–5 and other stones over the *décapage* surfaces (Modified after Salcedo Camacho 2012a: Fig. 88). (**b**) Unifacial artifacts of abrupt edge (on tabular block or flake): *1* – Double endscraper (Subphase 1B, Level 15); *2* – Simple frontal endscraper

microflakes (13,039; 66.58%), and chips (5074; 25.91%), while only 36 (0.18%) are tools: point preforms (4; 0.02%), Paiján-type points on flake (27; 0.14%; 25 of them were incomplete, two were complete, and one of them appeared outside the grid area), sidescraper (1; 0.01%), and retouched flakes (4; 0.02%) (Ugarte 2008: 47–48).

In early 2003, during the construction of the Camisea Pipeline Project, Luis Salcedo and his team recorded two new open-air sites in the area (Salcedo Camacho in press): Quebrada Cruz de Hueso 3 (QCH3) (150 masl; 12°20,8′ Lat.S; 76°46,8′ Long.W) is a huge preceramic dwelling site covering an area of 1.2 km^2, consisting of a series of shell middens (Fig. 3a) – where chanque (*Concholepas concholepas*) and a barnacle known as pico de loro (*Megabalanus psittacus*) predominate – as well as hearths and fullers on surface, associated with lithic workshops of basalt, quartz, etc., with the presence of hammerstones, *débitage*, and quartz foliated points (one of them was collected at 12°20,54′ Lat.S; 76°46,72′ Long.W) (Fig. 3b) and a possible burial area at the foot of a hill in southeastern quarter of the site; this site is better preserved than others in the area, because is flanked east and west by two small dry ravines, and its southern half is covered by tillandsias, which would have prevented erosion and the passage of all-terrain vehicles. Meanwhile, Cruz Quebrada West 4 (QCH4) (150 masl; 12°20,7′ Lat.S; 76°46,6′ Long.W) comprises two surface concentrations of malacological remains about 30 × 15 m each, separated by 20 m, with the presence of lithic material; the site was disturbed by Peruvian army artillery practices decades ago (Salcedo Camacho in press).

Tres Piedras

Tres Piedras PV35-3 quarry site (70 masl; 10°02,6′ Lat.S; 78°08,8′ Long.W) is a small outcrop of meta-volcanic andesite (originally described as "red porphyry") of 20 m in diameter, located less than 1 km northeast of Huarmey town, on the Pampa Tres Piedras of Huarmey valley, the same that was recognized and collected by Bonavia in 1977, yielding 237 lithic pieces (León 2002: 331–332). Two decades later, this assemblage was analyzed by Elmo León (2002: 334), who determined the presence of 32 point preforms, 204 flakes, and a hammerstone. León (2002: 329) indicates the recorded preforms are largely "failed trials (…) which (…) do not directly reflect the Paijanean operational chain," but were identified as "two successive knapping stages, compatible with minimum retouch pieces and the Chivateros–type preforms. Under a biface thinning criterion, it has been verified the knapper's attempts of lithic reduction, leaving typical debitage for each stage."

Las Gaviotas, Cerro Grande 1–4, Hacienda La Merced 1–2, and Pampa Del Vituco 1–3

In early 2003, during a survey for the coastal stretch of the Camisea Pipeline Project, several open-air sites with early evidence were located in San Vicente de Cañete (Cañete, Lima) (Salcedo Camacho 2014):

Central Andes: Prehispanic Hunter-Gatherers, Fig. 2 (continued) (Subphase 2B, Level 13); *3* – Snout endscraper or chopper (Subphase 3C, Level 2); *4* – Simple lateral endscraper (Subphase 3B, Level 6) (Modified after Salcedo Camacho 2012a: Fig. 124). (**c**) Unifacial artifacts of sharp edge (on flake): *1*, *2*, *3* – Modified *débitage* (Subphase 2A, Level 14; Subphase 2C, *Level* 12; and Subphase 3B, Level 5); *4*, *5* – Backed knife (Subphase 1B, Level 16; and Subphase 2B, Level 13); *6* – Simple convex sidescraper (Subphase 2D, Level 11) (Modified after Salcedo Camacho 2012a: Fig. 125). (**d**) Projectile point preforms (on block) and foliated points (on flake): *1*, *3* – Preforms fragments elaborated in andesitic tuff (Subphase 1A, Level 17; and Subphase 2C, Level 12); *2* – Preforms fragments elaborated in volcanic tuff (Subphase 2A, Level 14) (Modified after Salcedo Camacho 2012a: Fig. 128); *4* – Foliated point with ailerons in its middle third and serrated edges elaborated in red jasper, Lauricocha I/Arenal type (Subphase 1B, Level 15); *5*, *6* – Simple foliated points elaborated in silicified hematite (Subphase 2C, Level 12; and Subphase 2D, Level 10); 7 – Incomplete foliated point elaborated in silicified hematite, probable Lauricocha II/Canario type (Subphase 2D, Level 10). (Modified after Salcedo Camacho 2012a: Fig. 131) (All images: Archive of the CTM/PATL Archaeological Project 1995–1996)

Central Andes: Prehispanic Hunter-Gatherers, Fig. 3 Quebrada Cruz de Hueso 3 (QCH3) open-air site. The site and its artifacts. (**a**) General view of the surface of the site, showing the areas of shell midden, ash, and grinding tools. (**b**) Foliated point elaborated in quartz, probable Lauricocha II/Canario type; surface find. (Courtesy of TGP Exhibition Hall) (All images: Archive of the TGP Camisea Gas Pipeline Archaeological Project – Coast 2003–2004)

Las Gaviotas (LGav) site (95 masl; 12°57,7′ Lat.S; 76°29,7′ Long.W) is located in an area of dunes between hills above the (north) right bank of the valley of Cañete, halfway between the towns of Asia and San Luis de Cañete; it consists of two malacological concentrations associated to lithic material, being the largest and densest located east of the site (Salcedo Camacho in press); a small stemmed point of triangular blade, made of obsidian (Fig. 4), was recovered on the site's surface (12°57,72′ Lat.S; 76°29,77′ Long.W) (Salcedo Camacho in press).

Cerro Grande 1 (CG1) site (150 masl; 12°59,5′ Lat.S; 76°27,8′ Long.W) is located on the (north) right bank of the Cañete valley, in a currently desert area, where a huge elongated dune was lying through the site splitting it into two sectors; the site is a wide dispersion of malacological material with the presence of high-density lithic material and where an area of 21,606 m^2 was excavated (Salcedo Camacho 2014, in press). In Surficial and A layers, some projectile points of Lauricocha III/Corvina type (cf. Cardich 1958, 1964; Lanning 1963) were recorded, and between Layers B and D, several points of Lauricocha II/Canario type (cf. Cardich 1958, 1964; Lanning 1963) appeared, while in Layer G – a compacted ash matrix – typical points of the Proto-Lauricocha and Lauricocha I/Arenal type

Miniature lanceolate point of triangular blade, with serrated edges, asymmetrical shoulders, and small peduncle, prepared in obsidian; surface find. (Courtesy of TGP Exhibition Hall; Archive of the TGP Camisea Gas Pipeline Archaeological Project – Coast 2003–2004)

(cf. Cardich 1958, 1964; Lanning 1963) were recovered; this is the only known coastal site which presents the complete sequence of Lauricocha Complex's four stages (Salcedo Camacho 2014, in press) (Fig. 5a).

Lithic material recovered at the CG1 site comprises 32,629 items. In Sector A (CG1A), there are 20,501 items (62.83% of the overall total), of which 19,714 are chipped (96.16% of sector's total), belonging mostly to *débitage* (19,661;

Central Andes: Prehispanic Hunter-Gatherers, Fig. 5 Cerro Grande 1 and 3 (CG1 and CG3) open-air sites. Lithic artifacts. (**a**) Foliated points: *1* – Incomplete foliated point with ailerons in its lower third, Proto-Lauricocha type (CG1B, U7BC/Capa G); *2*, *6* – Foliated point with ailerons, Lauricocha I/Arenal type (CG1B, U7 BC/Layer G, and CG3B/surface find, respectively); *3*, *7* – Foliated triangular points of convex base (Lauricocha II/Canario type; CG1A, U3A/Layer A, and Evidence F3-E023a/surface find, respectively); *4*, *8* – Foliated rhomboid points, Lauricocha III/Corvina type (reference lost and CG3B/surface find, respectively); *5* – Foliated points with the maximum width in its lower third (CG1B, U7BC/Layer G). (Modified after Salcedo Camacho 2012b: Fig. 6, 2014: Fig. 154). (**b**) Miniature Fishtail-type point, crafted in red jasper, collected on the surface as Evidence F3-E023d. (Modified after Salcedo Camacho 2014: Fig. 109a; Photo: Courtesy of TGP Exhibition Hall) (All images: Archive of the TGP Camisea Gas Pipeline Archaeological Project – Coast 2003–2004)

95.90%) being sorted in cores (49; 0.24%), unmodified flakes (642; 3.13%), *cassons* (1465; 7.15%), and *debris* (17,505; 85.39%), while only 53 (0.26%) are tools (including 18 point preforms, 21 projectile points, 9 endscraper preforms, 18 sidescraper preforms, and 5 sidescrapers); it also has 787 (3.84%) non-chipped items, including manuports (710; 3.46%), blanks (16; 0.08%), hammerstones (16; 0.08%), spherical projectiles (9; 0.04%), polishers (22; 0.11%), grinding stones (3; 0.01%), straightener (1; 0.005%), and miscellaneous (10; 0.05%) (Salcedo Camacho in press).

Meanwhile, in Sector B (CG1B), there are 12,128 items (62.83% of the overall total), of which 11,950 are chipped (98.53% of sector's total), belonging mostly to *débitage* (11,911; 98.21%) being sorted in cores (22; 0.18%), unmodified flakes (676; 5.57%), *cassons* (445; 3.67%), and *debris* (10,768; 88.79%), while only 39 (0.32%) are tools (including 16 projectile points, 11 endscraper preforms, 7 sidescraper preforms, and 5 sidescrapers); it also has 178 (1.47%) non-chipped items, including manuports (155; 1.28%), blanks (11; 0.09%), hammerstones (5; 0.04%), spherical projectiles (5; 0.04%), polishers (1; 0.01%), and miscellaneous (1; 0.01%) (Salcedo Camacho in press).

Cerro Grande 2 (CG2) site (95 masl; 12°59,4′ Lat.S; 76°28,3′ Long.W) corresponds to a dispersion of malacological and lithic material on a flat area at the bottom of a ravine partially covered by dunes, being very disturbed by the passage of vehicles (Salcedo Camacho in press).

Cerro Grande 3 (CG3) site (165 masl; 12°59,5′ Lat.S; 76°28,0′ Long.W) is a dispersion of lithic material on the side of a hill partially covered by dunes, defining two sectors very similar to each other in material and density; a surface collection yielded two leaf points (Fig. 5a) and a lithic debris (Salcedo Camacho 2014, in press).

Moreover, Cerro Grande 4 (CG4) site (70 masl; 12°59,4′ Lat.S; 76°28,5′ Long.W) is also a dispersion of lithic material on the side of a hill partially covered by dunes, defining two sectors very similar to each other, also being very disturbed by the passage of vehicles (Salcedo Camacho in press).

A few meters north of the CG4 site, Evidence F3-E023d (80 masl; 12°59,34′ Lat.S; 76°28,4′ Long.W) was recorded lying on surface: a miniature Fishtail-type point (Fig. 5b) of about 3 cm length, crafted in red jasper (Salcedo Camacho 2014, in press).

About 3 km south of Cerro Grande sites, in the former Hacienda La Merced area, lies a huge jasper outcrop, a quarry which was exploited by the ancient inhabitants of the area as well as the Cerro Grande; surface erosion has caused the surrounding hills to be covered with reddish detritus, which gives a burgundy color to the entire surface of that part of the valley (Salcedo Camacho in press). Registered sites are as follows:

Hacienda La Merced 1 (HLM1) quarry (70 masl; 13°01,3′ Lat.S; 76°26,0′ Long.W) is on low hills, with soft slopes being covered with lithic material – basically high-density debitage – although Sectors A, D, and E appear to be preceramic, the site was reoccupied during ceramic epoch, given the presence of simple terraces (Sector B), some late windbreaks (Sector C), and the occasional occurrence of fragments of pottery and textiles (Salcedo Camacho in press). Lithic material recovered in HLM1 site consists of 4432 items, of which 4398 (99.23%) are chipped, belonging mostly to *débitage* (4373; 98.67%) being segregated into cores (623; 14.06%), unmodified flakes (866; 19.54%), *cassons* (1566; 35.33%), and *debris* (1318; 29.74%), while only 25 (0.56%) are tools (23 endscraper preforms and 2 sidescraper preforms); it also has 34 (0.77%) non-chipped items, including manuports (10; 0.23%), blanks (19; 0.43%), grinding stone (1; 0.02%), and miscellaneous (4; 0.09%) (Salcedo Camacho in press).

Moreover, Hacienda La Merced 2 (HLM2) quarry-workshop (55 masl; 13°01,2′ Lat.S; 76°26,9′ Long.W) is arranged on a plain which shows concentrations of high-density lithic material (Fig. 6), where different stages of the production process of lithic artifacts (quarry and workshop) are appreciated, while at the hilltops surrounding the plains, possibly contemporary windbreaks were found (Salcedo Camacho in press).

Finally, there are Pampa de Vituco 1, 2, and 3 sites: PV1 (160 masl; 13°14,2′ Lat.S; 76°16,9′ Long.W), PV2 (170 masl; 13°13,9′ Lat.S; 76°17,1′ Long.W), and PV3 (190 masl; 13°12,6′ Lat.S; 76°18,7′ Long.W); sites PV1 and PV2 are located on an plain, while the PV3 site is located in the northern and southern slopes of a hill; these are concentrations of lithic material located 35 km south of Hacienda La Merced, which include some nuclei, but mostly flakes and debitage made of jasper, being associated to malacological material (except at the PV2 site) (Salcedo Camacho in press).

Central Andes: Prehispanic Hunter-Gatherers, Fig. 6 Hacienda La Merced 2 (HLM2) open-air and quarry site. Lithic artifacts registered in situ. (**a**) Sidescraper crafted in andesite; (**b**) Two artifacts produced in silex: *1* – Modified *debris*; *2* – Blade. (All images: Archive of the TGP Camisea Gas Pipeline Archaeological Project – Coast 2003–2004)

Cerro Calcarí 6

In mid-2003, during rescue excavations carried out in the coastal stretch of the Camisea Pipeline Project, an area of 3321 m^2 was dug at Cerro Calcarí 6 (CC6) open-air site (145 masl; 12°27,2′ Lat.S; 76°43,7′ Long.W), a village-cemetery located at the bottom of the Calcarí dry ravine, Chilca (Cañete, Lima) (Salcedo Camacho 2014). This new site is not very visible on the surface, being located 3 km southeast of La Paloma site (Benfer 2000; Engel 1988; Quilter 1989) and about 5 km north-northeast of the Chilca Pueblo 1 site (Engel 1988), and accordingly it presents similar evidences registering its four cultural layers (named A–D) (Fig. 7a): semi-subterranean, round to oval dwellings raised by thin wooden posts and covered with vegetable fiber, associated to 25 human burials wrapped in mats crafted of plant fibers (Fig. 7b), presence of activity areas associated to hearths and ash dispersions, charred remains of animals and plants, and, in addition to plant material, malacological remains and lithic material (Fig. 7c) (Salcedo Camacho 2014, in press).

Lithic material recovered in CC6 site includes 1868 items, of which 1294 (69.27%) are chipped, belonging mostly to *débitage* (1265 items; 67.72%) being segregated into cores (5; 0.27%), unmodified flakes (285; 15.26%), *cassons* (274; 14.67%), and *debris* (701; 37.53%), while only 29 (1.55%) are tools (18 finished and 11 preforms, of which 20 are points, 4 are endscrapers, 4 are sidescrapers, and 1 is indeterminate); it also has 574 (30.73%) non-chipped items, including manuports (476; 25.48%), blanks (27; 1.45%), bludgeon or *porra* (1; 0.05%), fullers or *batanes* (4; 0.21%), mortar (1; 0.05%), grinding stones or *manos* (2; 0.11%), hammerstones (8; 0.43%), spherical projectiles (3; 0.16%), polishers (19; 1.02%), and miscellaneous (33; 1.77%), being the most used raw material basalt (31.0%), followed by quartz (10.3%) and quartzite (10.3%), with few obsidian (6.9%), diorite (6.9%), andesite (3.5%), and conglomerate (3.5%) (Salcedo Camacho in press). Although the site was not radiocarbon dated, lithic material is comparable to that of Chilca Pueblo 1 and La Paloma, about 6300–2500 years Cal. BC (Salcedo Camacho 2014).

Isolated Evidences at Lower Valley of Asia

In early 2004, during a survey for the coastal stretch of the Camisea Pipeline Project, near the Asia 2 site, located in the lower Omas valley, Asia (Cañete, Lima), four foliated projectile points (two triangular and two rhomboid) were discovered as isolated surface finds, registered as Evidences F2-E133a,b (Fig. 8a) and F2-E136a,b (Fig. 8b) (23 masl; 12°46′ Lat.S; 76°35′ Long.W), while cotton (*Gossypium barbadense*) fiber residues were recorded nearby (Salcedo Camacho 2014, in press).

Piedra Roja, Quebrada Huachoc, Quebrada Silla, and Huaynacoto 1

At least four preceramic open-air sites, of camp-workshop type, were identified from successive surveys conducted in 2003–2009 in hills and ravines at the left bank of Chancay middle valley, 25–40 km east-northeast of Chancay City (Huaral, Lima) (Goldhausen et al. 2008. 139–149):

Piedra Roja PV44-Q/01 site (1050 masl; 11°36,6′ Lat.S; 76°57,4′ Long.W) is located on a colluvial terrace, near a dry riverbed, at the southern foot of the Huachoc hills; lithic material collected includes debris, several tools, as well as bifacial preforms and stemmed points, one of them having a heart-shaped apex (Goldhausen et al. 2008: 142).

Quebrada Huachoc PV44-H/01 site (1080 masl; 11°33,9′ Lat.S; 76°57,8′ Long.W) is located on a colluvial terrace, over the northern slope of Huachoc hills; lithic material collected consists of debris, flakes, sidescrapers, and a stemmed point of triangular blade made of crystalline quartz (Goldhausen et al. 2008: 142).

Quebrada Silla PV44P/39 site (1650 masl; 11°26,1′ Lat.S; 76°52,6′ Long.W) is arranged on the top of a flat, low hill, extending to the adjacent plains; lithic material collected is more varied than the other sites, including amorphous cores, flakes, denticulates, plain cores, sidescrapers, some perforators, heavy grindstones, a bifacial preform, and a stemmed point (Goldhausen et al. 2008: 143–144), noting that some of the plain cores are similar to the "discoidal scrapers" of Lanning (1963).

Central Andes: Prehispanic Hunter-Gatherers, Fig. 7 Cerro Calcarí 6 (CC6) open-air site. Contexts and lithic artifacts. (**a**) North profile of unit U22; (**b**) Burial 4, adult male individual registered in unit U24 (Modified after Salcedo Camacho 2014: Fig. 172); (**c**) Foliated projectile points: *1*, *2* – Points with ailerons (U26F/Layer D and U58B/Layer C, respectively); *3* – Triangular point (U32F/Layer B1); *4*, *5* – Rhomboid point (U31B/Layer A and U1/Surficial, respectively); *6* – Point preform (U46/Layer C); *7* – Long foliated point (U39A/Layer C); *8* – Short foliated point (U31F/Layer B3). (Modified after Salcedo Camacho 2014: Fig. 173) (All images: Archive of the TGP Camisea Gas Pipeline Archaeological Project – Coast 2003–2004)

Central Andes: Prehispanic Hunter-Gatherers, Fig. 8 Surface finds in the Asia lower valley. Lithic artifacts. (**a**) Evidence F2-E133. *1* – Foliated triangular point, Lauricocha II/Canario type (F2-E133a; Modified after Salcedo Camacho 2012b: Fig. 5a, 2014: Fig. 153a); *2* – Foliated rhomboid point, Lauricocha III/Corvina type (F2-E133b; Modified after Salcedo Camacho 2012b: Fig. 5b, 2014: Fig. 153b [Drawing]). (**b**) Evidence F2-E136. *1* – Foliated triangular point, Lauricocha II/Canario type (F2-E136b); *2* – Incomplete foliated rhomboid point, Lauricocha III/Corvina type (F2-E136a). (All images: Archive of the TGP Camisea Gas Pipeline Archaeological Project – Coast 2003–2004; Photographs: Courtesy of Municipal Museum of Huaca Malena)

Finally, Huaynacoto 1 PV44-P/20 site (~1000 masl; 11°27,3′ Lat.S; 76°54,0′ Long.W) is located on the right bank of the Pacaybamba ravine, over a colluvial terrace placed at the foot of Viejo hill, which gives natural protection; the settlement consists of a set of small, semicircular residential structures of unworked stones and without mortar, arranged on terraces around a larger structure, although some of them were reused in ceramic epoch (Goldhausen et al. 2008: 149). Lithics were collected both inside and outside the structures and consist of cores (with or without platform), flakes (some retouched, other laminar), debris, choppers, thick endscrapers, plain cores, sidescrapers, knives, denticulates, a perforator, and some pounders, all made with a dark blue, medium-fine grain local rock (andesite?); also, there were preforms and finished points (including a triangular specimen of Lauricocha II type) made from blackish and whitish, fine-grained rocks (basalt and quartz?); in addition, some grinding stones were recovered (Goldhausen et al. 2008: 147, 149).

Las Brujas

Las Brujas rock-shelter (100 masl; 14°49,9′ Lat.S; 75°21,2′ Long.W) is located in the lower Río

Grande valley (Nazca, Ica), being excavated in 2007 and 2010 by Gabriela Ferrando by two 12 × 2 m trenches, yielding in layers 3–5 several occupation surfaces associated to hearths, botanical and shrimp remains, mollusk shells such as macha (*Mesodesma donacium*), and scarce lithic material, basically debitage, along with some nuclei, manuports, and polishers on quartzite and basalt, totaling 166 pieces (Ferrando 2011). The two dates obtained (Erl-13246 and Erl-13245) cover the range of 3360–2620 years Cal. BC.

Pampa Choclón 1–2; San Nicolás 3–4, 6–12, and 15–25; and EA-01 to 63

In 1963, the American Gary Vescelius reported three foliated points, and a coarse endscraper, associated to a large shell midden located in the beach of San Nicolas Bay, Marcona (Nazca, Ica) (Salcedo Camacho 2014: 427). During an initial evaluation of the area, Fernando Fujita, Juan Paredes, and their team recorded several open-air sites over the adjacent plains of San Nicolás (SN1–5) and Pampa Choclón (PC1–16), some of which are preceramic (e.g., PC1 and 2, SN3 and 4, although PC1 and SN3 were reoccupied in late ceramic period) (Salcedo Camacho 2015).

In mid-2014, Luis Salcedo and his team recorded new areas with lithic material in the plain adjacent to the San Nicolás Bay (SN6–12, 15–25, of which SN6, 10–12 have preceramic occupations, as well as potsherds associated with late windbreaks made of unworked stones, while SN7–9, 15–25 are clearly preceramic) and also in the nearby plain of Pampa del Choclón (PC17–23, of which only the small workshop PC19 is preceramic) (Salcedo Camacho 2015). Additionally, new lithic areas within the sites previously reported were found, particularly in SN3–4 and PC1–2; the PC1E Sector (130 masl; 15°15,6′ Lat. S; 75°10,7′ Long.W) (Fig. 9a) is remarkable, where several items produced from different raw materials were recorded, but especially of quartzite, as a chopping tool (Fig. 9b), large quartzite flakes and blades – some made out of the *outrepassé* technique (Fig. 9c, d) – and a Chivateros-type preform (Fig. 10a-1) (Salcedo Camacho 2014: 291).

Given the need to make viable the expansion work of Marcona Mining Project and considering all the evidence recorded were laying on surface (30–435 masl; 15°13,3′–15°14,2’ Lat.S; 75°10,9′–75°12,7′ Long.W), the three-dimensional and photographic record and consequent systematic collection of lithic material (areas with potsherds and malacological remains were avoided according to the mitigation plan) in those portions of the San Nicolás landscape where the various mining facilities (for processing and transportation of iron ore) will be built are proceeded; for such goal, only medium- to low-density areas were selected – called each one “archaeological evidence” (or EA’s in Spanish), followed by a sequential numbering – separating them from other, high-density areas (which were defined as “sites”: SN6, SN7, etc.); it has been estimated that the different surface concentrations and dispersions of lithic material in San Nicolás cover about 21 km^2 (Salcedo Camacho 2015, in press).

Such collection resulted in obtaining 17,362 chipped lithic items, each weighed and cataloged individually, of which a sample of 6537 items (37.65%) was thoroughly analyzed, belonging mostly to *débitage* (6470; 98,98% of the sample), being segregated into blade cores (11; 0.17%), flake cores (626; 9.58%), blades (59; 0.90%), flakes (4566; 69.85%), *debris* (671; 10.26%), and *cassons* (293; 4.48%); among the tools, sidescrapers (57; 0.87%) are relatively frequent, but endscrapers (16; 0.24%) and denticulates (3; 0.05%) are scarce, with the presence of various phases of point preforms (44; 0.67%), with some of them being quite large (Fig. 10a-2), being remarkable, while more advanced items in the reduction process seem to correspond to Fishtail point type (Fig. 10b-1) or to Paiján point type (Fig. 10b-2) (Salcedo Camacho 2015: 148–150). The large average size of the point preforms from Marcona even surpasses that recorded in Cerro Chivateros, which until then held the record, regarding the size of Casma specimens and those of the original Paiján area of the north coast (cf. León 2002: 331).

Polished material is too scarce, limited to a broken hoe and a cylinder (totaling 0,05%);

Central Andes: Prehispanic Hunter-Gatherers, Fig. 9 Pampa Choclón 1 – Sector E (PC1E) site. The site and its artifacts. (**a**) General view of the site's surface, showing the areas of secondary quarry of quartzite, basalt, and jasper. (**b**) *1*, *2* – Front and side views of a chopping tool crafted on quartzite. (**c**) *1*, *2* – Front and side views of a quartzite flake obtained with the technique of *outrepassé*. (**d**) *1*, *2* – Front and side views of a basaltic rock blade obtained with the technique of *outrepassé*. (All images: Modified after Salcedo Camacho 2015; Archive of the SHP Marcona Mine Expansion Archaeological Project 2014–2015)

all mentioned lithic material comes from San Nicolás area, except a point preform and a chopping tool from Sector PC1E (Salcedo Camacho 2015: 148).

The most common raw material is by far quartzite and its variants (totaling 82.57%), while among the siliceous rocks, varieties of jasper (8.03%) are included, with silex (1.51%) and chert (0.21%) being scarce; among siliceous materials, there are chalcedony (0.52%) and milky quartz (0.03%), being both scarce, while among volcanic rocks, andesite predominate (4.74%), followed by basalt (1.82%), rhyolite (0.32%), and dacite and its variants (0.16%), with diorite (0.02%), granodiorite (0.02%), and granite (0.02%) being very few; additionally, there has been a piece of magnetite ore (0.02%) as well as two pieces of unidentified raw materials (0.03%) (Salcedo Camacho 2015: 148).

San Nicolas lithic industries are mostly primary, carrying out the initial work of reducing the blanks (quarry *facies*), which in vast majority are regular- to large-sized pebbles, with large pebbles of basalt and quartzite being used as hammerstones, as well as green or yellow jasper nodules, some of which show traces of percussion like extremely large flake negatives; thus, the existence of two clearly defined lines of the *chaîne opératoire* was determined: those that produce flakes and those that produce blades (Salcedo Camacho 2015: 148).

Central Andes: Prehispanic Hunter-Gatherers, Fig. 10 Secondary quarry sites of Pampa Choclón PC1E, San Nicolás SN12B, and Evidences EA-43 and 46 of San Nicolás. Spear point preforms at different stages of knapping, all produced in different varieties of quartzite; surface finds. (**a**) Pieces in early stages of reduction. *1* – Chivateros-type preform (PC1E, Finding 1) (cf. Salcedo Camacho 2014: Fig. 109c); *2* – Early stage preform (SN12B, Finding 1). (**b**) Pieces in late stages of reduction: *1* – Probable Fishtail-type preform (Evidence EA-43q77); *2* – Probable Paiján-type preform (Evidence EA-46a20). (All images: Modified after Salcedo Camacho 2015; Archive of the SHP Marcona Mine Expansion Archaeological Project 2014–2015)

Central Asia: Paleolithic

Marcel Otte
Université de Liège, Préhistoire, Liège, Belgium

C

Introduction

Abundant evidence demonstrates the existence of Lower Paleolithic occupations in Tadjikistan and Kazakhstan more than a million years ago (Ranov 1965, 1972; Derevianko 2004), like those discovered in China. However, the Zagros region contains different cobble industries similar to the Oldowan (Otte et al. 2004). Cultural contact thus occurred between Central Africa and Southern Asia from at least 2 million years ago (Figs. 1 and 2). This dual interference, from Eastern Asia and Eastern Africa, affected this key region: Asia in its northern area and Africa in these southern areas. This fundamental setting describes all later populations and civilizations intermediate between Africa and Asia. Like elsewhere in the world, these technological trends fused and were standardized to form the Middle Paleolithic, with a shift to lighter tools. At this time, around 200,000 years ago, investment shifted from blocks of raw material (cobbles and bifaces) to the production of retouched flakes that were much smaller and adaptable and that could be used for a broader range of tasks. Nonetheless, persistence in some aspects took place despite this strong pattern. The northern plains developed Levallois

Central Asia: Paleolithic, Fig. 1 Iranian Azerbaijan, polyhedral (Otte et al. 2004)

Central Asia: Paleolithic, Fig. 2 Qazialiad, chopping tools, Iran (Otte et al. 2004)

technology, which is based on the careful preparation of cores to produce predetermined flake forms that were then retouched and used. Conversely, the mountainous areas of the south show intense reduction due to intense reuse of tools, retouching, and hafting, resulting in short tools. This pattern makes the "Zagros Mousterian" found in Turkey, Iraq, and Iran similar to the European Mousterian "Quina" facies (Otte et al. 2006). This industry is the basis for subsequent innovations leading to the Upper Paleolithic. Archaic modern humans are associated with this Mousterian facies, found at Shanidar (Iraq), Denisova (Altaï), Teshik-Tash (Uzbekistan), anatomically equivalent to the European Neandertals (Solecki 1998). The associated burials confirm as well their spiritual capacities.

Key Issues/Current Debates/Future Directions/Examples

The dichotomy observed during the Middle Paleolithic between the Zagros Mousterian and the northern Levallois blade industry continues until the onset of the Upper Paleolithic. In the mountainous areas, the trend toward bladelet (very small blades) production on thick flakes led to the Aurignacian in the west, via the Baradostian cultures in the Zagros region (Otte et al. 2009) (Figs. 3, 4 and 5). With thrown weapons (in which bladelets were the points of small projectiles), techniques became oriented toward the processing of bone with all of the associated symbolism: ritual death of the animal, killing at a distance, and using animal products themselves to kill other animals (Fig. 6). This revolution, reflected in simply technological domains, thus corresponds more profoundly to a new attitude of humans with respect to their existence and place in nature. It also implies the occasional mounting of animals (e.g., horses) and the use of dogs for transport using the travois (Germonprez et al. 2009).

This new attitude, as much as such modes of transport, explains both the demographic explosion in Central Asia and population expansion to east and west, where they would be called Aurignacian. This tripartite relationship established between techniques, religion, and transport is seen, for example, in the creation and spread of pendants, a sort of trophy from a successfully vanquished animal. These decorative elements come from the natural defenses of the animal, canine teeth, and ivory, and thus embody their formidable and dangerous qualities. By their display, they designate the rank of the wearer both in the environment and in human society. The continuity of these processes in Central Asia appears natural and fundamental and contrasts logically with the abrupt movements that external migrations to the far southwest of Europe accentuated.

In parallel, the northern plains also underwent a lightening of tool size with techniques shifting from the production of Levallois blades to thinner blades and bladelets: Obi-Rakhmat in Uzbekistan (Derevianko 2004) and Kara-Born in the Altaï. Ultimately, this different demographic pressure spread to the west for reasons similar to the spread of the Baradostian, but on the northern plains and somewhat later, under the general term Gravettian.

Central Asia: Paleolithic, Fig. 3 Jabrud, Aurignacian (Syria). (After Rust, in Otte and Kozlowski 2007)

The evolutionary sequence in Central Asia was oriented toward the production of thinner, even microlithic, blanks, called the Zarzian in Iran. These microlithic armatures demonstrate the extreme development of small projectile points and indicate the widespread use of the bow and arrow, and thus the particular relationship of man with nature. The precision, rapidity, and long distance left little chance to the animal, which had become a dietary resource rather than mythical inspiration. In this form, 10,000 years later, the European Mesolithic and the Jomon culture in Japan are identical (Otte 2010). The Neolithic is very early in the Zagros Mountains with animal herding and permanent houses built of solid materials (Braidwood 1960). Due to its location and demographic density, Central Asia is an active center affecting its neighboring regions. We see here the development of modern anatomical morphology for this part of the world. The

Central Asia: Paleolithic, Fig. 4 Shanidar, Aurignacian (Iraq) (Otte and Kozlowski 2011)

origin of techniques for throwing weapons and conquering mythologies also find their regional source here.

In all prehistoric periods, Central Asia functioned as a reservoir for populations and cultural experiences, seasoned by clear but sporadic external influences. The original population may have come from southern Asia (Meganthropus) or East Africa (*Homo ergaster*). However, the best comparisons for the first known industries (made on cobbles) are clearly from Africa (Oldowan culture). The bifacial tool tradition on massive blocks (Acheulean culture) also comes from East Africa. This long history is supported by evidence for the occasion closing of the straits: Bal-el-Mandep and Ormuz. This entire southern Asian zone seems to have formed a geographic and cultural unit extending from the African lakes to the Siwalik Mountains in Pakistan, India, and Nepal, for which the Zagros Mountains form the center of gravity. With the smaller tools of the Middle Paleolithic, regional diversification and technical solutions increase. In the southern regions, caves served as refuges and stone materials were transported to them in already reduced form. Everything was in place for a shift to exploitation of hard animal materials (bone, antler, ivory) and to the microlithization of stone armatures. The Aurignacian solution resulted from this combination. Demographic increase was a consequence of this trend and led to migrations as far as Western Europe. Conversely, the northern plains, with abundant materials of good quality, saw continuity but based on Levallois principles. The entire western Gravettian still shows traces of this. Central Asia then underwent evolution toward microlithization and then Neolithization, both particularly early. Technological innovations, renewal of religious systems, and anatomically evolved populations spread rapidly along a longitudinal axis, largely open via the steppe landscapes and the temporary drying of interior seas. Central Asia determined a good part of European prehistory and apparently also that of the Punjab region in northwest India. To understand this immense region also enables explanation of many events observed along its borders, in the Near East and Europe.

Central Italy: Etrusco-Italic Sanctuaries

Ingrid Edlund-Berry
Department of Classics, The University of Texas at Austin, Austin, TX, USA

Introduction

Sanctuaries had many functions in the societies of ancient Italy. As places of worship of one or more deities, they provided gathering places for individuals and groups and therefore attracted human endeavors such as trade and production of goods. While there is little evidence for how individuals expressed their own private religious beliefs, they definitely displayed their public practices of sacrifices, offerings, and other rituals.

Although Rome rose to become the politically most powerful city of ancient Italy and the Mediterranean, the ancient Roman historians were the first to acknowledge her debt to the neighboring peoples in Central Italy. As early as the Iron Age (ca. 1000–700 BCE), each community shared many features with its neighbors in terms of buildings (mostly huts), burials (mostly cremation), and production of pottery (impasto), but there were also distinct differences in their daily lives. Although we do not have direct evidence of the languages spoken in Central Italy before the development of writing, continuity of other traditions suggests that forms of Latin and related languages (Faliscan, Osco-Umbrian) as well as the non-Indo-European Etruscan language were in use. Evidence for religious practices in Central Italy varies greatly depending on the archaeological remains and on written sources, whether local inscriptions or general historical accounts.

Definition

In terms of defining sacred spaces and sanctuaries, the common denominator seems to be the importance of choice of location and, depending on historical circumstances, continuity of cult. Offerings of pottery and other objects occur in close connection with the natural setting of mountains, caves, rivers, or springs as well as within communities and at burial grounds (Edlund 1987). If buildings were erected at such locations during the Iron Age, they can be identified as sacred by their location and use, rather than by the architectural form, and it is not until the Orientalizing (700–600 BCE) and Archaic (600–475 BCE) periods that sacred buildings, including temples, can be documented. During the early Roman Republican (475–300 BCE) and mid- to late Roman Republican (300–31 BCE) periods, creation and expansion of sanctuaries were part of the political and historical changes caused by the expansion of Rome while at the same time providing continuity of cult in communities and in the countryside.

For the purposes of this discussion, the area included covers the territory of Rome and her immediate neighbors, the Etruscans to the north as far as the Arno; the Faliscans, Sabines, and Umbrians to the north and east; and the Latins and Samnites to the south (Fig. 1). As can be expected, our written sources for Rome overshadow those of the neighboring peoples, and if we were to believe the Roman historians, both political and cultural initiatives began in Rome and were imposed on their neighbors in a one-way direction.

In viewing the archaeological remains of sanctuaries throughout Central Italy, it will, however, be clear that the historical development is quite complex and that Rome was part of a broad cultural context of exchange and interdependence in many fields, including forms of religion and their expression in sanctuaries. A key issue is to identify the common factors in the creation of sanctuaries and to follow the development of forms that spread throughout the Mediterranean and also inspired much of later European architecture.

Although Central Italy represents only a small area of the peninsula and the Mediterranean as a whole, the study of its sanctuaries provides an example of balancing written and archaeological sources with the understanding that both have to be interpreted with caution. In particular, for the study of architectural form, we are dependent on the account of the Roman architect Vitruvius, whose important work *On Architecture* (Rowland and

Central Italy: Etrusco-Italic Sanctuaries, Fig. 1 Map of Etruria and Central Italy (Created by Beth Chichester and Ingrid Edlund-Berry)

Howe 1999) provides valuable information on Roman temples that, however, cannot automatically be applied to time periods other than his own, the time of Augustus. Likewise, archaeological remains of temples built in communities that came under Roman authority are often regarded as Roman *Capitolia*, created at the time when the Roman or Latin colonies were founded, but may in fact reflect a combination of cultural and political interests (Edlund-Berry 2017).

Sanctuaries and Temples

Within the broader topic of sanctuaries in Central Italy, textual and archaeological evidence provides information on location and relation to settlements, historical context, layout, architectural features of temples and other buildings, areas for offerings and sacrifices, and continuity of cults. While temples tend to stand out because of their size and decoration, they are part of the larger context of the sanctuary and its historical and religious importance (ThesCRA 2005).

Sanctuary Sites and Their Locations

The type of cult and the needs of its worshippers determined the location of sanctuaries. Cults for the living were linked to places of habitation, travel, or trade, whereas funerary cults were practiced at burial sites outside the boundaries of inhabited areas. As indicated by ancient authors such as Vitruvius, certain deities had specific requirements for the location of their sanctuaries, that is, for Jupiter, Juno, and Minerva as protectors of a city a high vantage point; Isis and Serapis in the marketplace; Apollo and Liber (Bacchus) next to the theater; Hercules by gymnasia, amphitheaters, or the circus; Venus by the harbor; and Vulcan (as well as Venus and Mars) outside the city (*De arch*. 1.7.1). By analyzing the location of sanctuaries, their relation to nature and human habitations, and the evidence for cults and rituals, patterns emerge as to what determined the original choice of spaces and later modifications (Colonna 1985; Edlund 1987).

Access

Depending on the natural features of the landscape, a sanctuary would most likely be visible from afar and aligned with other sacred places along the roads and paths (e.g., the site of Brolio in Val di Chiana and the temple at Castiglion Fiorentino). The orientation of sanctuaries and their point of access were most likely determined by the cults practiced and natural features such as the sea (e.g., temples at Pyrgi). Since temples and altars seem to have been oriented in the directions prescribed according to the divisions of the sky, often independently of each other (Prayon 1997), visitors and worshippers could not necessarily expect to approach these structures by the most convenient or easiest route.

Boundaries and Precincts

The boundaries of a sanctuary could be determined by natural features (streams, mountain tops, woods) or by man-made features such as roads or boundary stones (Edlund-Berry 2006). Within a sanctuary precinct (known as *sacellum* or *locus consaeptus*), smaller units, usually centered around an altar, provided further distinctions of space and the transitions from one area to the next (Colonna 2006; Stek 2009). Because of find circumstances, the full extent of a sanctuary precinct may be difficult to determine (e.g., Orvieto, Campo della Fiera [Stopponi 2011, 2014]).

Sanctuaries in Nature

The connection between sanctuary sites and their geographical setting in nature is best documented by observation of context. Visibility, access, connection with paths, and roads for travel and transhumance are all relevant factors, in addition to the perceived notion of identifying deities with features of nature.

Finds of pottery, bronze, or stone and habitation of caves from the Bronze Age provide evidence of continuity into the Iron Age. Although it may be difficult to identify ritual activities, continuity of use suggests that certain places have been perceived as sacred throughout the early history of ancient Italy. Many of these remained open-air places for sacrifices and offerings, while others were incorporated into settlements or created to satisfy changing demands. As clearly defined spaces, *templa*, the function could thus dominate over the original location in nature.

Urban Sanctuaries

According to Servius, the late Roman commentator to Vergil's *Aeneid*, an Etruscan city should include three temples as well as three gates and streets (*Ad*

Aen. 1.422), and, as can be expected, the location of urban sanctuaries took into account both the nature of the settlement (such as hills and access to water) and the demands of the cults and their practitioners. It is therefore not surprising to find Rome's most important temple to Jupiter, Juno, and Minerva located on the Capitoline Hill, visible from the public area, the Roman Forum below, from the neighboring hills, and from the river Tiber. Depending on the layout of the settlement, temples occur on hills, within the areas of habitation or separated from them (Rome, Marzabotto, Veii, Orvieto [Fig. 2], Civita Castellana, Tarquinia, Fiesole) or as part of the public spaces such as fora (Rome, Pompeii, Roman and Latin colonies).

While sanctuaries may have begun as open-air sanctuaries within a future urban space, urban sanctuaries proper are likely to include temples and altars as their key features. Depending on their origin and function, the access to the temples was tied to roads, but the orientation was governed by the cults practiced.

Extramural Sanctuaries

Many sanctuaries are placed immediately inside or outside city boundaries, including city walls. As such they protected the city inside while at the same time marking the transition from inside to outside and identifying the type of boundary, whether or not marked visually.

Depending on the landscape, extramural sanctuaries could be placed at the foot of a hill (Veii, Portonaccio temple) or at city gates (Vulci), whereas in cities built on spread-out hills such as Rome, there existed two if not three kinds of boundaries: first, the confines of each hill; second, the outline of the political-religious boundary known as *pomerium*; and third, the man-made city walls (Servian and Aurelian walls) that determined the territory of the city as a whole (Richardson 1992).

Extra-Urban Sanctuaries

Depending on the size and political structure of towns in Central Italy, their territory could be protected by sanctuaries serving as outposts but also as points of contact with neighboring communities. Inland cities such as Caere or Tarquinia were connected with the Tyrrhenian Sea, thanks to their ports at Pyrgi and Gravisca, and sanctuaries there provided important links for trade as well as cults.

Rural Sanctuaries

Sanctuaries in the countryside reflect both cults of rural residents and of travelers between communities. Examples include votive deposits along roads, in the fields, and at river crossings (Colonna 1985; Edlund 1987). As indicated by ongoing surveys and excavations, our knowledge of the countryside is expanding greatly, and as contexts are becoming better known, the term rural sanctuaries should be redefined to apply to those that are specifically related to the farms and the fields, previously perhaps thought to have been isolated. It is also possible to link some seemingly rural sanctuaries to a major central sanctuary (e.g., Pietrabbondante [Stek 2009]) for which they served as boundary sanctuaries.

Federal or "Political" Sanctuaries

According to Roman historians such as Livy and other sources, the Etruscans held meetings for a coalition of their major 12 (or 15) cities at a sanctuary of Voltumna (Edlund 1987). Neither the exact location nor the appearance of this sanctuary is defined in the texts, but the area of Orvieto has been suggested as a likely spot (Fig. 3), and recent excavations at a site just to the south of the city, known as Campo della Fiera, may well meet the criteria for this important gathering point (Stopponi 2011). Features in favor of the identification include the large size of the sanctuary, the number of altars, and the evidence of offerings, as well as the long tradition that this site was used for gatherings (hence the name Fiera or "market"). Remains of a temple have been uncovered, but to date there has been no definite identification of the deity honored there.

Throughout Italy, sanctuaries have been identified in the written sources as political centers under divine protection, ranging from urban temples (e.g., temple of Diana on the Aventine in Rome) to mountain sanctuaries (*Mons Albanus*, south of Rome; temple of Diana Tifatina at Capua), groves, and markets (Lucus Feroniae), but without historical texts or inscriptions, it is often difficult to identify such sites based solely on the archaeological evidence (Edlund 1987; Stek 2009).

Viewed from the point of view of the architectural form, monumental buildings consisting of rooms on three or more sides of an open courtyard such as those at Poggio Civitate (Murlo), Montetosto (near Caere), Acquarossa (near Viterbo), and Satricum illustrate spaces suited for residence as well as for gatherings of large numbers of people (Edlund 1987). Although lacking obvious evidence of sacred rituals (temple, altar), such

Central Italy: Etrusco-Italic Sanctuaries, Fig. 3 Orvieto, view (Photo: Ingrid Edlund-Berry)

structures may well have had many functions, including gatherings for a political and religious purpose under divine protection.

Historical Background

The historical context of sanctuaries is tied to the communities to which they belonged, and, understandably, the best textual evidence comes from Rome. Here, in addition to the actual remains of temples, the records of temple foundations and dedications allow us to follow the long history of early cult places (e.g., the area of Vesta) to the first temples (S. Omobono) and the most monumental temple ever built in Central Italy, the Capitoline Temple, which stood as the symbol of the city's divine protection well into the imperial period. Other temples were erected as the result of Roman military victories (temple of Castor in the Roman Forum, Republican temples in the Forum Holitorium and Campus Martius) or in recognition of new deities introduced to Rome (temple of Apollo Medicus, temple of Asclepius) (Richardson 1992). Construction of temples is sometimes tied to the important patronage of individuals or families (e.g., the Tarquins for the Capitoline Temple in the sixth century BCE), whereas inscriptions record other activities in sanctuaries, including vows and offerings.

Outside Rome, the creation of new sanctuaries and temples is often linked to the political and historical process in which Rome expanded within the Italian Peninsula and ultimately throughout the Mediterranean. As part of this process, new cities were laid out, with public spaces, including temples honoring the chief Roman deities, Jupiter, Juno, and Minerva. In the Roman provinces outside Italy, these temples, commonly referred to as Capitolia, usually located in connection with a forum, are easily recognizable by their tall podium, front porch with columns, and three rooms in the back for the cult statues (ThesCRA 2005). Within Italy, new temples were often built in connection with the establishment of Roman or Latin colonies, but it is not given that they were intended to reflect a connection with the Capitoline Temple in Rome, in spite of having the characteristic three-cella plan. At Cosa (Ansedonia), founded as a Latin colony in 273 BCE, a major temple was built at least 100 years later, and while usually considered modeled on the Capitoline Temple in Rome, its function has recently been doubted (Bispham 2006). Similarly, temples built in the Latin colonies of Sora (Liris valley) (Fig. 4), founded in 303 BCE, and Isernia, founded in 263 BCE, are often categorized as Capitolia and may illustrate a close dependence on Rome but may also be part of a broader Etrusco-Italic tradition (Edlund-Berry 2008). It can therefore be misleading to use the term Capitolium for any temple built outside Rome, even if inspired by Roman temple planning and cult practices, and the chronology of such temples cannot be tied directly to the foundation dates of colonies. Regardless of the historical umbrella under which a temple was created, the term Capitolium should be used with caution and the temple building be evaluated within its geographic and cultural context (Bispham 2006).

C

Key Issues/Current Debates

Layout of Sanctuaries

Sanctuaries represent sacred spaces that may include a number of buildings and other monuments as well as spaces for performing rituals.

Architectural Features of Temples and Other Buildings

The buildings associated with sanctuaries include temples, defined as structures holding the cult statue, and small shrines (*sacellum*, *naiskos*) used for a variety of cult activities. In addition, permanent or temporary structures may have been needed for the priests and assemblies of worshippers to provide lodging, dining areas, and other facilities. Pools or basins provided means of ritual cleansing if required as part of the activities at the sanctuary (Veii, Portonaccio). Natural slopes or man-made theaters (Pietrabbondante [Fig. 5]) could be used for gatherings or ritual activities. Production of votive offerings of clay or metal further required workshops and kilns, in addition to raw materials and fuel.

Temples

In Latin terminology, the word *templum* indicates a defined space used for ritual purposes such as the observation of signs sent by the deities. As a building, a temple was considered the home of the deity, where a cult statue or other objects would occupy the main room (*cella*). If the temple was dedicated to more than one deity, then two or more cult rooms were included in the building (ThesCRA 2005).

Location

The location of a temple was determined by the other features of the sanctuary, and it is likely that the boundaries of the sanctuary were defined before a temple was constructed. Although the sanctuary precinct cannot be identified for all

Central Italy: Etrusco-Italic Sanctuaries, Fig. 5 Pietrabbondante, temple and theater (Photo: Ingrid Edlund-Berry)

sanctuaries, the location and orientation of the temple seem to be independent of other structures, with the possible exception of a main altar.

Orientation

According to Vitruvius (*De arch*. 4.5), the orientation of temples was based on several factors, related to both the cults and the surrounding areas. Ideally, a temple should face west so that the worshippers will view the cult statue within the temple with the rising sun in the east as a backdrop. Other considerations were to place the temples in such a way that the city walls were clearly visible, or to line them up near public roads to facilitate access.

Other criteria for the orientation are based on the division of the sky and the earth as documented on the Etruscan bronze model of a sheep's liver, the so-called Piacenza liver, and the text by the late Roman author Martianus Capella (Prayon 1997). Depending on the deity to whom the temple was dedicated, during the Archaic period, the favored orientation for the Etrusco-Italic temple was toward the south and unrelated to the layout of the urban context. After the Archaic period, new and restructured temples were more likely to be coordinated with the city plan and surrounding structures.

Plan and Proportions of Temples

In addition to describing the ideal location for temples (*De arch*. 1.7.1), Vitruvius classifies temples by their plan, based on the positioning of columns (3.2). Of the seven types mentioned ("*in antis*," prostyle, amphiprostyle, peripteral, pseudodipteral, dipteral, and hypaethral), Vitruvius is careful to include examples from Rome when these could be found, that is, for the "*in antis*" plan, the temple of Fortune; for the prostyle, the temple of Jupiter and Faunus on the Tiber Island; for the peripteral, the temple of Jupiter Stator and the temple of Honor and Virtus; and for the dipteral, the temple of Quirinus.

Likewise, Vitruvius discusses the number of columns and their relation to each other and the temple proper (*De arch*. 3.3). The categories (*species*) include pycnostyle, systyle, diastyle, araeostyle, and eustyle, of which the last is considered ideal. The examples included for Rome are for the pycnostyle the temple of Deified Julius and the temple of Venus in the Forum of Caesar, for the systyle the temple of Equestrian Fortune, for the diastyle the temple of Apollo and Diana, and for the araeostyle the temple of Ceres near the Circus Maximus and the Capitoline Temple.

Proportions

While the preserved temples represent different sets of proportions, the theoretical model is presented by Vitruvius who defined different categories of temple architecture, based on what he perceived as perfect numbers and proportions (*De arch*. 3.1–2). This principle is parallel to his definition of the ideal proportions of the human body, in which the foot is one component. Measured in numbers, the Roman foot equals about 29.5 cm., whereas the Oscan foot is slightly shorter, c. 27.5 cm. Of these, the Oscan foot is used, for example, at the Orientalizing and Archaic buildings at Poggio Civitate (Murlo) (Nielsen and Tuck 2001: 39), whereas the Roman foot is recorded at the sanctuary at Campo della Fiera (Orvieto) (Stopponi 2011: 26–7, n. 31).

The Tuscan Temple Design

The terminology for much of Greek and Roman architecture is based on Vitruvius, whose descriptions of the three main types (*genera*), Doric, Ionic, and Corinthian, have influenced architectural theory as well as practice since antiquity. Following his analysis of these types, he presents the Tuscan design, according to which the plan centered on certain proportions (six parts in length, five parts in width), arranged with a front porch with columns and a rear part with three rooms or one room with wings on the sides (Fig. 6) (*De arch*. 4.7.1–5). The columns and superstructure were also to be planned with a fixed ratio of height and diameter in relation to the base, the shaft, and the capital. Vitruvius further prescribes that the types can be mixed so that Tuscan and Corinthian or Ionic features are combined (*De arch*. 4.8.5).

In applying Vitruvius' analysis of the "Tuscan" temple design, it is important to realize that his

Central Italy: Etrusco-Italic Sanctuaries, Fig. 6 The Tuscan temple (with permission from Rowland and Howe 1999)

terminology is different from other references to the Italy of his day where he uses the common Latin vocabulary for Etruria, Etruscan, or Tuscan (*Etruria*, *Etruscus*, *Tuscus*). Instead, the temple architecture is referred to as "*tuscanicus*," a word that implies something Tuscan-like or Tuscan-inspired rather than a description of the early Etruscan architectural styles of the Archaic period (Edlund-Berry 1997).

Archaeological Evidence

Vitruvius' description is often quoted as the norm for Etrusco-Italic temples, but the archaeological evidence provides a much more varied picture.

While examples of his "Tuscan temple" with a squarish plan, three cellae, and a colonnaded front porch indeed exist, at other times evidence is lacking for the features he prescribes, including the meaning of the Latin word *ala*, usually translated as "wing" (Lake 1935).

The classic example of the Tuscan temple is the Capitoline Temple in Rome, constructed during the reign of the Etruscan kings of the Tarquin dynasty but inaugurated in the first year of the Roman Republic, 509 BCE, by M. Horatius. In spite of the incomplete remains, the foundation of the temple, elements of the superstructure, and coin images allow for a reconstruction of the temple with three cellae and a colonnaded front porch. The dimensions of the temple as reconstructed are, however, so massive (54 × 74 m.) that it dwarfs all other temples from Central Italy and instead shows links with Greek monumental temples (Davies 2006).

Although Vitruvius' description of the "Tuscan temple" is applicable to a number of temples in Central Italy, it is prudent to separate the political function of the Capitoline Temple in Rome from any temple with a similar plan. Rather, by following the development of early cult buildings in the shape of huts and simple one-room roofed structures (Satricum, Tarquinia, Veii, Pyrgi), we see that temple buildings were created to serve the local tastes, whether in the form of peripteral temples (Pyrgi, temple B; Vulci, Tempio grande; Marzabotto; Satricum) or temples with one or more cellae and a colonnaded porch (Rome, S. Omobono; Veii, Portonaccio; Pyrgi, temple A; Rome, temple of Castor; Ardea; Orvieto, Belvedere temple; Fiesole).

Archaeological Remains of Temples

Because of the perishable materials used in constructing Etrusco-Italic temples (and other buildings), every element of the preserved remains can be used to evaluate the plan and function of the building.

The foundation of the temples usually consists of local fieldstones or of cut blocks of volcanic or other rock. Vitruvius describes the necessary steps for securing a proper foundation course, above which the podium provides the visible support for the temple building proper (*De arch*. 3.4). The podium varies in height and decoration, with key elements consisting, from the bottom up, of a plinth (*quadra*), base molding (*spira*), dado (*truncus*), cornice (*corona*), and top molding (? cavetto; *lysis*) (Rowland and Howe 1999: Fig. 45).

As can be expected, the preserved temples display a variety of types of foundations, with or without a podium defined with moldings. Although in all likelihood the Roman temples Vitruvius would have seen in his lifetime had podia with top and base moldings, each city or area seems to have followed its own traditions. The earliest preserved examples of podium moldings (Rome, S. Omobono, Pyrgi, Satricum) seem to have a small Etruscan round marking the top row of the podium, whereas later podia include two rows of Etruscan rounds of equal size, or with one large and small round, sometimes separated by vertical plain blocks (Rome, S. Omobono, Ardea). At other times, there is no evidence of a molding, which may or may not have existed (Rome, Capitoline Temple). The Etruscan round continues to be in use throughout the time of the Roman Republic and is found at sites such as Pietrabbondante (temple A). It was also used in temples built in towns where Roman or Latin colonies were founded (Sora, Isernia, Cosa) or in areas under Roman dominance (Villa S. Silvestro near Cascia) and may indicate a sense of continuity of architectural traditions even as Rome herself began to explore the cyma reversa molding which was adapted from Greek forms mixed with variations of the curved Etruscan round (Rome, Largo Argentina, temple C) (Edlund-Berry 2008). As the cyma reversa molding becomes dominant, most temples in Central Italy displayed it as a top and base molding, at times in combination with or replaced by the cyma recta molding toward the end of the Roman Republic.

Walls of early temples were usually built of clay, reinforced with wood and occasionally of tuff blocks. Postholes may indicate the place for wooden columns that supported the walls and the roof.

While remains of foundation walls and other features on the ground provide evidence for the

reconstruction of temples and other sacred buildings, models of buildings, usually in the form of urns for cremation burials, suggest different types of roofs. In the models that resemble Iron Age rounded or oval huts, the roof is shown as thatched with wooden crossing beams for stability. Later rectangular models indicate tiled roofs and sometimes ornamental akroteria along the ridgepole or at the ends.

In addition to such models, Vitruvius' statement about araeostyle temple roofs suggests that they made the building look top-heavy and low (*De arch*. 3.3.5). It is, however, roof tiles that provide the best source for estimating the superstructure and for reconstructing temples for which even the foundations are no longer preserved. The basic roofing system consists of flat rectangular pan tiles, curved cover tiles, and large curved ridgepole tiles. Analysis of the clay composition and firing can provide clues for the production sources, and the local differences in size of the elements suggest chronological sequences of roofing systems, including new construction and replacements (Winter 2009). Estimates of the total weight of a roof also facilitate reconstructions of walls and supporting columns, with or without preserved foundation courses (Turfa and Steinmeyer 1996).

In addition to the actual roof covering, terracotta plaques provide information about the roofing elements, including horizontal beams and rafters, and indicate the methods used for drainage (Fig. 7). Most of these types of architectural revetments are mold-made, and a study of the clay components, mold sequences, and size of the individual plaques (e.g., the use of the Oscan foot) provides evidence for the number of roofs, estimated size of the buildings to which they pertained, and technical details such as the slope of the pediment or size of the eaves. These terracotta revetments were often decorated with painted or relief designs or mold-made features such as human or animal heads, which further assist in documenting workshops or trade exchange between different towns and communities in Central Italy (Winter 2009).

In addition to the terracotta revetments, many temple roofs were decorated with statues of deities or human figures, animals, or floral elements, placed along the ridgepole or at the end of the roof as akroteria. As with the scenes depicted on the revetments, the motifs of the akroteria illustrate myths that usually are not related to the deity or deities to which the temple was dedicated. Although terracotta decoration, including akroteria, is common on sacred buildings such as temples, it occurs also on buildings used for other purposes, whether public or private (Winter 2009).

Places of Gathering and Residence

All sanctuaries, regardless of function, relied on a central location and good access, but those that served many different communities would by necessity include spaces for gathering of people as well as quarters for priests and other officials. A particularly good example is the important Samnite sanctuary at Pietrabbondante that houses not only temples and a theater complex but also a structure identified as a *domus publica* for the priests, similar to that in Rome and Pompeii (La Regina 2010).

Altars

Altars for sacrifice and prayers are present at most sanctuaries and occur in many different forms. The primary example with altars ranging from irregular mounds of small stones to squares or rectangles built of tuff blocks comes from the important sanctuary at Pyrgi (Colonna 2006). In addition to the different forms of these altars, the variety of votive offerings, many of which include imported objects, and remains of sacrifices provide evidence of the cultic activity at the sanctuary. Other types of altars consist of freestanding blocks, often with double round Etruscan moldings, found within the Etruscan and Latial territories (Orvieto, Fiesole, Lavinium, Rome, Ardea, Pieve Socana [Fig. 8]) throughout the Archaic and Republican Roman periods (ThesCRA 2005).

Areas for Sacrifices, Offerings, and Other Ritual Activities

Offerings to the dead were made at the gravesites, but there is also evidence of small shrines (Tuscania, Ara del Tufo; Blera, Grotta Porcina) or monumental steps leading up to a platform

Central Italy: Etrusco-Italic Sanctuaries, Fig. 7 Architectural revetments (with permission from Winter 2009)

adjoining a tumulus grave (Cortona, Il Sodo) (Colonna 2006). Funerary cults may have required sources of water (Orvieto, Cannicella) or altars for sacrifices. On occasion burials are found in non-funerary contexts, perhaps suggesting human sacrifice and ritual burials (Tarquinia, Civita [Bonghi Jovino 2010]).

In addition to burnt animal sacrifices, common forms of offerings include miniature vessels probably containing food and liquids, bronze or terracotta statuettes of deities and worshippers, pottery, jewelry, coins, and other objects. While many of the objects were locally made or traded, others were imported from afar. Offerings can be found in dug pits ("votive deposits") or distributed over large areas of the sanctuary.

Rituals at sanctuaries required defined spaces, including areas for sacrifice, usually in connection

Central Italy: Etrusco-Italic Sanctuaries, Fig. 8 Pieve Socana, altar (Photo: Ingrid Edlund-Berry)

with altars, and inspection of the sacrificed animals (hepatoscopy). Spaces were also set aside, for observation of signs in the sky (including haruspicy and brontoscopy) and for prayers and other rituals presented by priests, perhaps in conjunction with the altar in front of a temple and the steps leading up to the cult statue inside the temple.

In addition to sacrificial meals, evidence of dining rooms with couches and pottery for eating and drinking would suggest that meals were taken in the sanctuary by participants and spectators. Depending on the distribution of local sanctuaries within an area, visitors to a sanctuary would also need lodging and places to conduct business.

Continuity

What remains today of ancient sanctuaries, including temples, seems to be the result of chance as well as intentional preservation. Some sites that were completely covered over by earth or sand (Ardea, Fosso dell'Incastro) have been rediscovered, whereas others have been visible continuously because of temple foundations built into churches and other buildings (Rome, Sora). At times the historical evidence confirms conversion of sanctuary sites to other uses (Pietrabbondante after the Social War [La Regina 2009]), whereas accounts of disruption such as the "calling out" (*evocatio*) of Juno from Veii after the Roman conquest of 396 BCE may be exaggerated (Stek 2009).

International Perspectives

The continued study of Etrusco-Italic sanctuaries has added to our appreciation of the form and function of sacred spaces. Although monumental temple structures were important throughout the ancient Mediterranean, different traditions, including the use of perishable building materials, have at times skewed our understanding of ancient cultures and their religious expressions. It is therefore important to incorporate the temples and sanctuaries of Central Italy into a broader geographical and chronological framework as evidence for human activity documented primarily through archaeological evidence.

Future Directions

The most concrete result of a thorough study of Etrusco-Italic sanctuaries will be to reevaluate the history and development of architectural traditions in Rome and surrounding areas. Whether we define "Roman" as a chronological or cultural term, buildings, including temples, were part of life in the city of Rome proper, and Roman architecture is therefore as ancient as the city herself, with a modest beginning in the Iron Age. It is, however, important to try to separate the political advancement of Rome from her assumed role as innovator of art and culture and to explore the interaction of all the peoples of Central Italy that gradually resulted in a uniform Italo-Roman culture, spearheaded by Rome.

Central Italy: Pre-Roman and Archaic Ceramics

Marijke Gnade and Jeltsje Stobbe
Amsterdam Archaeological Centre, University of Amsterdam, Amsterdam, The Netherlands

Introduction

The study of pre-Roman ceramics covers the field that deals with ceramics produced and used in the central part of Italy (Etruria, Latium, Campania)

between the eleventh and the late fifth/early fourth century BCE. The area is considered to have a more or less similar material culture during this time span, and pottery research is usually carried out within shared thematic frameworks. The field is firmly grounded in typological analysis of grave goods, as (especially Etruscan) funerary archaeology has played an important role in the study of pre-Roman ceramics. In the past decades, interest has risen significantly in pottery coming from settlement excavations, and typological research of necropoleis is now complemented with a variety of sherd-based approaches such as technological analysis and statistics. As in the case of typological studies, these are often presented as part of a one-site study. General overviews or syntheses on pre-Roman pottery are therefore mostly found in original research publications, in exhibition catalogues, or in conference volumes that have become iconic over time.

The period of pre-Roman ceramics can be roughly subdivided into the Iron Age (eleventh to late eighth century BCE), the Orientalizing period (late eighth century BCE to late seventh/early sixth century BCE), the Archaic period (late seventh/early sixth century BCE to late sixth century BCE), and the Late Archaic period (late sixth/early fifth century BCE). The manufacturing of pottery in the Iron Age is done in households, but this slowly evolves into a workshop production from the Orientalizing period onwards, when the lifestyles of emerging local elites go hand in hand with craft specialization and the use of new pottery technologies. Mass production and distribution of both kitchen/storage wares and table wares only starts in the later Orientalizing and Archaic periods within the context of the emergence of urban environments in Central Italy.

Definition

Pre-Roman ceramics concern kitchen/storage wares such as impasto and coarse ware and table wares such as fine impasto, bucchero, and the painted wares (Italo-Geometric and Etrusco-Corinthian). Other functional categories of fired clay include small architectural ceramics such as building blocks, roof tiles, and architectural terracottas; weaving tools such as spools, spindle whorls, and loom weights; figurative objects such as small clay figurines; cooking stands and stoves; and pottery stands. Most ceramic categories are not decorated and contain only a slipped, smoothened, or burnished surface. The table wares, however, are known for their decorations which can be painted, incised, impressed, or attached.

Historical Background

From the eleventh century BCE onwards, small hut villages slowly developed into proto-urban centers in Etruria, followed shortly by Latium and Campania. The proto-urban centers would become the monumental city-states of the seventh and sixth centuries BCE (Bietti Sestieri 1992). These developments occurred in tandem with a change from egalitarian communities to hierarchical societies. An "aristocratic ideology" emerges from the ninth/eighth century BCE onwards. Elites practice this ideology through the use and display of luxury items imported from the Near East and of new lifestyles including hero cults, gift exchange, and a Greek-inspired wine drinking ritual, the symposion (Bartoloni 2003; also Riva 2010). Women might have played some role in these activities as well: pottery that can be associated with the drinking and banqueting rituals as well as remains of wooden chariots have been found in burials of both sexes (Rathje 2000; Bartoloni 2003).

Whereas the aristocratic ideology is mainly expressed through funerary rituals in the Iron Age and Orientalizing period, there is a shift in the manner of expression from the later Orientalizing period onwards. The "heroic" cremations and "princely" burial mounds and chamber tombs with their large sets of grave goods give way to the embellishment of monumental sanctuaries and their rich votive deposits and to the construction of large private houses with stone foundations and tile roofs (Colonna 1988). This shift in expression is associated with a consolidation of power by elites but at the same time seems

to be reinforced by an emerging middle class that promotes the mass production of formerly high value or elitist goods (Colonna 1979; Bartoloni 2003).

The mass production of goods is the result of a gradual craft specialization. In the later Iron Age and the Orientalizing period, local elites start controlling production and distribution of certain goods, often in so-called temple economies, and favor a specialized (mass) production of votive and funerary goods. The arrival of Greek and Phoenician traders in western Mediterranean waters from the ninth/eighth century onwards played an important role in this intensification of production. Greek traders, or even migrating Greek potters, can be held partly responsible for the introduction of new ceramic technologies such as the use of depurated clays, the potter's wheel, and a more efficient and controllable firing technique. Although the importation of Greek pottery (and of overseas trade in general) diminishes in the later Orientalizing period, the new technologies are now applied on a large scale in local pottery production. This forms the basis for the emergence of specialized workshops in the Archaic and Late Archaic periods (Nijboer 1998).

Key Issues

Impasto

Impasto is the most common pottery ware throughout Italy from the Early Iron Age until the Archaic period (eleventh to early sixth century BCE). At the same time, it is the pottery category with the loosest of definitions. Generally said, impasto concerns locally made pottery of non-depurated clay with a smoothed to burnished surface. Although impasto as a term is in use since the sixteenth century for the act of mixing water with clays and inclusions (Camporeale 2001), it is introduced as an archaeological term only in the late nineteenth century for handmade pottery made of non-depurated clay (Cuomo di Caprio 2007). In literature on ancient technologies, impasto can also refer to the actual mixture of clays used for pottery production (Cuomo di Caprio 2007). The term can also be used to describe burnished coarse wares used until Roman times.

A division is made between impasto of the Iron Age and impasto of the Orientalizing period. Impasto of the Iron Age concerns handmade pottery that is built up of coils or slabs of heterogeneous clays. The surface color varies due to the use of an open-air firing process at low temperatures, and it ranges therefore from red to very dark brown and black. Decorations can be incised (geometric motifs), plastic (cords or knobs), pressed (ribs or ripples), or cut (channels or grooves). The most common shapes are small storage jars and cooking jars, lids, bowls, cups, plates, spindle whorls and spools, cooking stands, pottery stands, and shapes used in funerary rituals such as biconical vases and (hut) urns. Although a utilitarian ware, impasto can be found in all kinds of contexts – including funereal, votive, and domestic (Camporeale 2001; Bartoloni 2002) (Fig. 1).

Central Italy: Pre-Roman and Archaic Ceramics, Fig. 1 Iron Age "dinner service" found in a dwelling on the site of ancient Satricum (modern Le Ferriere, Latina). (Courtesy and copyright Groningen Institute of Archaeology)

At the end of the Iron Age, technology and taste start to change: clays become partly depurated, surface colors are more homogeneous due to better firing control, and narrative decorations appear alongside geometric motifs. The shape repertoire continues within the traditions of the Iron Age, but some shapes are inspired on metallic prototypes of the Near East (Camporeale 2001) and on Greek and Phoenician pottery styles (Bartoloni 2003). During the Orientalizing period, shapes become more and more standardized. This is the result of the emergence of craft specialization and the beginnings of a workshop mode of production (Nijboer 1998). The main table wares of the Orientalizing period are brown burnished impasto (impasto bruno) and red burnished – sometimes slipped or even painted – impasto (impasto rosso). Other less frequent categories include buccheroid impasto and the painted wares red-on-white (Fig. 2) and white-on-red (or "sub-geometric"; see further below) and a coarser version of impasto with a burnished surface (impasto grezzo) (De Lucia Brolli and Benedettini 2000). The various shapes of these categories are associated with the diffusion of wine drinking, either as a practice of seated drinking or as a practice of recumbent banqueting. Although evidence of local wine drinking practices seems to exist for the Early Iron Age – while banqueting practices surely existed – the intensification of both wine drinking and banqueting is usually associated with the dissemination of Greek and Phoenician elite customs in Italy. An example of impasto pottery associated with wine drinking is, for instance, the Aegean-inspired pottery stand that can carry a large (mixing) crater or the two-handled kantharos that serves as a drinking cup, but also more indigenous impasto shapes are considered to have been part of such a ceremony, examples being the spiral amphora that might have served for drinking and the biforate handle cup that was probably used to transfer wine from crater to cup (Bartoloni 2003). A famous example of a complete banqueting set in a domestic context has been found in Ficana (Latium), among which was found an oversized impasto rosso pottery stand accompanied by a large wine mixing basin (Fig. 3).

In the later seventh century BCE, standardized pottery makes its appearance. Clays are tempered, a wheel is used, firing is done under controlled conditions in a closed oven, and surfaces are more often slipped or smoothed instead of burnished. The Archaic coarse ceramics of the sixth century make their first appearance and for the most part replace impasto as the main common-ware pottery (see further below).

Bucchero

Bucchero is the primary table ware of Central Italy in the seventh, sixth, and fifth centuries BCE. It is known for its distinct black surface color with high sheen and its specific shape repertoire. The first use of the term dates back to the years around the turn of the eighteenth century when Portuguese imitations of pre-Columbian ceramics labeled "pocaro" or "búcaro" were exported to Italy, and their resemblance to the newly discovered Etruscan pottery style gave bucchero its name (Camporeale 2001). Although bucchero has often been labeled as the national pottery of Etruria, it is clear now that it was also produced in non-Etruscan areas of Central Italy.

Bucchero is usually subdivided into bucchero sottile, bucchero pesante, and grayish bucchero. Bucchero sottile stands for very thin-walled handmade bucchero that has been mostly found within tombs in southern Etruria of the second and third quarters of the seventh century BCE. It is characterized by a shiny black surface color and a very dark core. The color of bucchero, the decorative motives, and the productive technologies have often been considered as indicative of imitations of oriental-style metal wares (Hirschland Ramage 1970), but the later date of metal wares makes it very likely that bucchero might have been a prototype itself (Camporeale 2001). Most probably diverse branches of craftsmen worked closely together on high-quality goods such as metals, ivory, and pottery and meanwhile mutually influenced one another in the production process (Gran-Aymerich 1995). The distinctive surface and core color of bucchero are (arguably) established by reducing the atmosphere during the firing process which turn iron oxides from red into black, while the surface sheen is achieved through intense polishing before firing (Cuomo di Caprio 2007; Perkins 2007). The shape repertoire has clearly evolved out of eight-century impasto shapes, and it might well be that bucchero was produced alongside other kinds of pottery such as impasto. Examples of this continuation are the spiral amphora (Fig. 4) and the very popular and widespread kantharos, kalyx, and kyathos. On the other hand, shapes such as the kotyle, the olpe (Fig. 5) and the skyphos are clearly derived from the Corinthian pottery repertoire (Camporeale 2001).

The south Etruscan city of Caere is considered as the first production center of bucchero sottile and starts to produce and export bucchero in the early seventh century BCE. Other production centers soon follow in south Etruria and Campania,

and in the later seventh century, bucchero is produced throughout the major part of Italy. Potters might have travelled between cities, especially in the case of Campanian bucchero: its strong resemblance to Caeretan bucchero indicates that either the bucchero or the potters might have been originally from Caere. In this period bucchero is considered a luxury table ware associated with wine drinking. Initially it is only used by elites, who display it in tombs as drinking services, offer it in sanctuaries, or use it in their aristocratic houses as ordinary ware for personal use or for special occasions such as a drinking party in symposion style. The value attached to the ware is made clear through the many vases showing ownership inscriptions (Camporeale 2001).

After a transitional phase (Hirschland Ramage 1970), bucchero evolves into bucchero pesante, the thick-walled bucchero of the late seventh and the first half of the sixth century. Bucchero pesante has a slightly coarser clay and a more dull sheen than bucchero sottile and shows signs of standardization of shape and decoration when compared to the earlier bucchero. Decorations are now mostly in relief by using tools such as roller seals to make impressions (Fig. 6), by attaching plastic decorations or by pressing the clay; these can consist of floral or animal motives and narrative scenes. Initially, bucchero pesante is produced in large quantities and exported abroad to regions such as Greece, the Levant, the north African coast, the Iberian peninsula, and southern France. However, in the sixth century, bucchero is distributed more closely to its production center and is possibly in use by an emerging urban middle class which tries to imitate the customs of the elites (Camporeale 2001).

From the middle of the sixth century onwards, bucchero loses its distinct black sheen and grayish bucchero makes its appearance. Grayish bucchero is often not considered as proper bucchero, due to its gray surface color and light core. Surface treatments can vary from low burnished to slipped, and

shapes are limited to predominantly low-footed bowls, jugs, and table amphorae. Despite a decline in quality, it remains a popular ware in tombs, sanctuaries, and domestic contexts throughout Central Italy.

Painted Wares

Italo-Geometric and Etrusco-Corinthian pottery are the main painted wares between the eighth and the sixth centuries BCE. Although both are inspired by Greek prototypes, they differ in style and date. Italo-Geometric pottery is inspired on the Euboean Geometric pottery of the middle of the eighth century and ignores the rise of Corinthian styles from the late eighth century, whereas Etrusco-Corinthian pottery is exactly an imitation of Corinthian styles, although only from the later seventh century onwards.

Italo-Geometric (or Etrusco-Geometric) can be executed in both a depurated and an impasto (as in non-depurated and burnished) version. Although the clays and most shapes are local, the decoration motives such as concentric circles, triangles, meanders, series of parallel or wavy lines, and checkerboards are clearly derived from Greek examples. This Greek connection has led to the idea of the first workshops of Italo-Geometric pottery being run by Greek craftsmen (De Lucia Brolli and Benedettini 2000; Gaultier 2001).

The oldest Italo-Geometric pottery is made in southern Etruria from the middle of the eighth century onwards alongside local impasto, and it closely follows Euboean examples (Bartoloni 2003). Despite the influx of new objects and styles from the Near East in the later eighth century BCE, the Italo-Geometric potters continue to stick to the Euboean Geometric motives. Even Corinthian objects that start to appear from the late eighth century onwards do not change their mind, although hybrid shapes or Greek-style shapes used for wine drinking and banqueting rituals are now made as well. This later phase of Italo-Geometric pottery is labeled sub-geometric and continues to be produced in only specific areas of Central Italy (Gaultier 2001).

A very recognizable subgroup of the sub-geometric pottery carries a characteristic decoration of metope friezes with geometric motives. These geometric schemes are here and there replaced by a more free figurative painting style which appears on vessels of depurated clay but also on burnished red impasto (the so-called white-on-red ware) (De Lucia Brolli and Benedettini 2000) (Fig. 7). This is one of the last geometric styles to be found in Central Italy. At the end of the seventh century, the influence of Corinthian pottery starts to play its decisive role, and the Etrusco-Corinthian pushes the Geometric off the stage of table wares (Gaultier 2001).

Etrusco-Corinthian (or Italo-Corinthian) pottery is a table ware inspired by the large influx of Corinthian pottery from the later seventh century onwards. Etrusco-Corinthian pottery is made of a depurated clay and has a painted decoration in which the Greek black-figured technique figures prominently. It can be difficult to distinguish Etrusco-Corinthian pottery from its prototype, especially when it is found in a fragmentary state in settlement contexts. Fortunately much has become known about the hands of various

Central Italy: Pre-Roman and Archaic Ceramics, Fig. 7 Storage jar in white-on-red ware from southern Etruria with a lid in the shape of a drinking cup. The red burnished surface shows a painted decoration of two panthers sharing a head (at the back side two facing lions). (APM15400; courtesy and copyright Allard Pierson Museum, Amsterdam)

painters which can be used to distinguish between local workshops (Szilagyi 1992).

Initially, Etrusco-Corinthian pottery follows Corinthian models closely, and pouring vessels such as oinochoai and olpai, the alabastron perfume flask, and amphorae become highly popular in elite lifestyles. As in the case of Etrusco-Geometric and bucchero pottery, most Etrusco-Corinthian shapes probably serve in an elitist wine drinking or banqueting setting, although they are found in domestic contexts, sanctuaries, and tombs alike. However, from the beginning of the sixth century, Etrusco-Corinthian pottery becomes mass-produced. This mass production is probably to be associated with the needs of an emerging middle class that tries to imitate the elites, as in the case of thick-walled bucchero. The mass production is short lived, as around the middle of the sixth century, production shifts from large vases to small luxury items such as perfume flasks (alabastra and aryballoi; Fig. 8) and pyxides. Three easily recognizable main motif groups can be distinguished in this period: a group of human masks, a group of birds, and a group of facing roosters. These are the last testimonies of local pottery inspired by Corinthian models, as from the middle of the sixth century onwards, Etrusco-Corinthian pottery is gradually replaced by imported and imitation Attic black-figured pottery (Gaultier 2001).

Coarse Ceramics

Coarse ware or "ceramica grezza" (in Italian) is one of many names given to the wheel-made and mostly undecorated pottery of coarse fabric which is found in large amounts in settlement contexts from the early sixth century BCE onwards. For this reason it is also called domestic ware or ordinary ware, in Italian literature referred to as "ceramica comune" or "ceramica di uso domestico," but other names occur like utilitarian ware or kitchen ware, referring to the everyday function of the pottery. Other terms used are red-brown impasto, impasto grezzo, Archaic impasto, or wheel-made impasto in order to distinguish the ware from the earlier handmade, coarse impasto.

The term coarse ware was introduced by Einar Gjerstad in his publications on Early Rome of the 1960s. Giovanni Colonna used the term to indicate a distinct group of pottery within the larger class of impasto coming from the excavations of the area of the S. Omobono sanctuary in Rome (Colonna 1963–1964), whereas Murray-Threipland used the term for the development of this class of pottery during the fifth century in her studies on the pottery from Veii (Murray-Threipland 1963). Recent publications on excavations in Rome and Satricum (Carafa 1995; Bouma 1996; Gnade 2002) also use the term coarse ware and provide detailed typologies based on size and form/morphological aspects (Steures 1992; Carafa 1995; Bouma 1996).

The clay of this pottery is easily distinguished from that of the Iron Age impasto as it is characterized by a clearly visible presence of inclusions consisting of a wide array of mineral particles (mica, augite, biotite, olivine) as well as pieces of crushed pottery, small stones, and large amounts of fine sand. There appears to be a marked resemblance between the fabrics of the large vessels and those of the architectural elements, above all the roof tiles. This has been

Central Italy: Pre-Roman and Archaic Ceramics, Fig. 8 Etrusco-Corinthian aryballos used for perfume. (APM10559; courtesy and copyright Allard Pierson Museum, Amsterdam)

noted in Satricum (Latium) where the fabric of the earliest dark-red Archaic roof tiles, characterized by the natural presence of ferromanganese (FeMn) nodules, can be paralleled in the large storage jars (dolia); a similar correspondence can be noted for the later Archaic products where the clay of the roof tiles like that of the large basins is characterized by identical mineral elements among which rather large and irregularly shaped particles of augite. Given the mutual resemblance in fabrics, it may be suggested that architectural elements were produced in the same workshop as the larger vessels (Angelelli 2001; Gnade 2002). Another observation regards the color of the coarse ceramics which through time changes from dark to light, reflecting some chronological development within the Archaic red-firing and the Late Archaic pale-firing clays. For the fifth and fourth centuries, a predominance of orange fabric is observed probably due to higher firing temperatures.

In general the surface of the coarse ceramics must have been covered with a thin slip, the color of which matched that of the fabric. Often only slight traces have remained due to the course surface of the pots. Painted decoration is known from a clearly defined group of coarse white ceramics which occurs in many Central Italian settlements from the beginning of the sixth century and is variously defined as Late Italo-Geometric, referring to the painted bands (Gjerstad 1953); as cream coarse ware (Torelli and Treipland 1970) and as "ceramica sabbiata chiara" or "impasto chiaro sabbioso" (Angelelli 2001), referring to an obviously sandy quality of the clay; and as "impasto chiaro augitico," referring to the abundant presence of augite particles in the clay (Clementini and Rossi Diana 1988).

The repertoire of coarse ceramics shapes is rather limited and consists of four or five basic forms which show a considerable degree of uniformity per individual shape, suggesting a limited series of production centers that served large areas. The few basic shapes show continuity throughout the sixth, fifth, and fourth centuries BCE which makes it awkward, at the present stage of study, to make clear chronological distinctions in the individual shapes. Small differences in the forms of lips, rims, and bases have been used to establish detailed typologies of the individual shapes, but as it appears, this morphological approach seems of rather limited value to establish detailed chronologies for this material (Slej and Cullhed 2008).

The most common shape is the globular-ovoid, flat-based storage and/or cooking jar of medium size, also called neckless jar ("olletta" in Italian), which often displays traces of secondary burning on the bottom and lower half of the pot (Fig. 9). This particular shape is produced in enormous quantities in the fifth and fourth centuries BCE and continues until the Imperial period, be it in a different type of fabric. In the fourth century, the high-rimmed jar makes its appearance, though a few earlier specimens dated to the fifth century are known, often with a characteristic almond-shaped thickening on the outside of the lip and notably thin-walled. At the same time, the bodies of the later jars start to display plastic decorations like one or two encircling thin plastic cords, either plain or with finger impressions (Bouma 1996).

Central Italy: Pre-Roman and Archaic Ceramics, Fig. 9 Coarse ware neckless jar or olletta used for cooking. (Photo by Anneke Dekker, copyright Satricum Project/University of Amsterdam)

A much larger variant of the storage jar is the dolium, characterized by its thick outcurving rim often profiled with encircling grooves. This jar is sometimes provided with heavy grips or lugs placed on the shoulder. The fabric of this shape changes through time, from a rather friable quality in the Early Archaic period, probably due to low firing temperatures, to a more consistent, hard-fired quality. The early dolia often display a dark-red burnished surface. A smaller version of the storage jar shows large ring handles horizontally attached on the shoulder.

The shape associated with the neckless jar is the conical lid/bowl with wide spreading walls which served two functions. It is characterized by a proper knob which may be solid or ring-shaped, sometimes with upturned edges ("a becco a civetta") or edges decorated with impressions produced by the fingertip or a small stick. It occurs in many different sizes, suggesting that the shape was made independently from the jar. Flattened, disk-shaped lids without knobs can be attributed to the dolia.

Among the other open shapes within the repertoire are the basin-like vessels, either with high, spreading walls (trays) or with curved walls (basins). The first shape, also known under the Italian names "bacino" or "teglia," shows four lugs attached to the bottom. These are rounded, triangular, or tongue-shaped and often show fingertip impressions. A few "teglie" have an encircling finger-impressed cord decoration below the rim. The lugged tray becomes en vogue from the late seventh century BCE onwards and continues to be produced with some minor formal changes until the late fourth to early third centuries BCE (Colonna 1963–1964; Bouma 1996). With regard to the function of this shape, it has been suggested that it may have served as a "testum," a kind of cover placed over a hearth through which a small oven was created. The bottom of the "teglia" could then serve as a baking plate (Zifferero 2004). A variation of the teglia type, which may be considered a later development, shows curving walls and a T-shaped rim. It often displays an encircling plastic ridge, with or without fingertip impressions, and is sometimes provided with two heavy, vertical loop handles attached on top of the rim (Gnade 2002; Argento 2006). When produced in light-colored clay, the vessel may be painted with red-brown or black encircling bands whereas the rim may show diagonal painted stripes.

The second shape, a wide and rather shallow basin of hemispherical shape (called mortaio in Italian), occurs from the second half of the sixth century BCE and has as its main characteristic a lip with band-shape thickening on the outside of various thickness and profile (Gnade 2002). It is sometimes provided with a spout. The clay of these basins is mainly light-colored containing many inclusions; many basins display encircling painted bands on the interior as well as the exterior of the vessel.

During the fifth and fourth centuries BCE, the production of coarse ware pottery continues with a larger range of shapes, more thin-walled and hard-fired.

Fine Wares

Fine wares continue to be produced alongside the coarse ceramics of the sixth and fifth centuries BCE, though their presence is less conspicuous than that of the latter category. Grayish bucchero of a poor quality is known from various sites. It often shows a flaking surface or slip which at times may also be red. In fact there exists a category of pottery that was produced alongside the gray bucchero and which is characterized by a very recognizable red slip for which it has tentatively been defined as reddish bucchero (Steures 1992). Its first occurrence is attested in the late sixth century, and it continues to be produced during the fifth and fourth centuries when the quality of the product seems to dwindle (Gnade 2002). A common ware for Satricum and known also from the Faliscan area, it occurs only sporadically in other Latial sites. The shape repertoire is limited to bowls and jars (Fig. 10).

The fifth century also witnesses the first appearance of black-gloss or black-glazed pottery (Italian: *vernice nera*), fine textured table ware with a characteristic shiny black-slipped surface. This pottery will soon become the main fine ware product in Central Italy and entire Mediterranean region.

Central Italy: Pre-Roman and Archaic Ceramics, Fig. 10 Red slipped bowl, also called red bucchero. (Photo by Anneke Dekker, copyright Satricum Project/ University of Amsterdam)

Future Directions

Pre-Roman pottery represents many different ceramic classes which, apart from the traditional typological studies, encompass also other possibilities for research, the results of which can be mobilized to tackle issues such as the technology of pottery production and its organization, the mechanisms and intensity of pottery distribution, and patterns of consumption and use of pottery. To this end, a systematically executed and integrated approach of geological sampling and technological analysis of the various ceramic classes, i.e., a combined mineralogical and chemical analysis, is opportune. This approach should not be limited to individual ware classes in individual sites and in particular periods but ideally should cover much longer periods and larger areas. Through the acquired data, a better understanding can be reached of the mechanisms underlying production and consumption processes and related commercial activities.

Different initiatives in this particular field of research have already been undertaken, especially with regard to Roman pottery from the middle/late Republican periods (Olcese 2006). However, a similar, large-scale, and integrated research is still lacking for the earlier, pre-Roman ceramics in the geographical regions of Central Italy. An abundance of ceramic material excavated in the nineteenth and twentieth centuries is stored in dusty storerooms and has not been looked at after an initial processing. Usually, only a very small proportion of the excavated ceramic material, the so-called diagnostics, is published in excavation reports or in typological studies. A situation which is regrettable considering the time and effort put into the collection of the material and considering the fact that much of the so-called non-diagnostic ceramics is not as non-diagnostic as it seems. It could tell us a lot more when more attention will be paid to those features that have been previously neglected in processing the ceramics.

Introduction

Archaeological and paleo-landscape records from the Pacific Islands offer material examples of how people have sustained themselves through several centuries or millennia of fluctuating sea level affecting their island habitats, access to freshwater sources, resource ecology, and capacity to sustain growing populations. The lessons from the past bear relevance for understanding future management challenges around sustainable livelihoods in the face of unprecedentedly rapid climate change. The factual records have revealed what was successful or unsuccessful about how people in the past responded to the changing sea-level conditions over a long time span. These records invariably transcend periods of different sea levels and climates that affected the entire Pacific region, and therefore they are suitable for identifying cross-regional correlations between specifically attested natural processes and cultural behavioral responses.

At a global scale, sea level has changed according to the world's average temperature affecting the amount of water trapped in glaciers and ice sheets, as well as the expansion or contraction of ocean surface water. Periods of colder temperature have resulted in lower sea level, most conspicuously during the world's ice ages or glacial periods. Conversely during interglacial periods, such as the Holocene Epoch in which we are now living, large amounts of ice melted and thus flooded the world's oceans. In addition to these impressive events that affected sea level by more than 120 m in some cases, more frequent minor fluctuations of sea level have occurred on the order of a few meters, commonly as a result of temperature variations even of just a few degrees C.

The Pacific Islands present ideal settings for measuring the elevations of current versus ancient tidal notches, coral reefs, and lagoon facies that are directly datable by radiocarbon and other techniques. In other regions, observations of tidal notches by themselves have not always enabled the same confidence in their dating without the related occurrences of coral reefs or other associations that have retained datable contents abundantly along the coasts of tropical Pacific Islands. Furthermore, evidence from multiple islands all across the Pacific has allowed the identification and isolation of localized anomalies such as from tectonic movements to be separated from the region-wide picture.

Archaeological excavations have demonstrated a cultural presence in the Pacific Islands primarily within the last 4000 years, encompassing a number of fluctuations in the regionally documented sea-level history (Fig. 1). Owing to the major ice melting that was triggered at the beginning of the Holocene about 10,000 B.C., sea level over several centuries approached modern conditions and in fact peaked across the entire Pacific region at 1.5–2 m higher during the mid-Holocene highstand at approximately 3000–1000 B.C. (Mitrovica and Peltier 1991). After the highstand, sea level began a period of drawdown over the next several centuries. A slight sea-level rise occurred during the Little Climatic Optimum (LCO) at A.D. 750–1250

Central Pacific Islands: Sea-Level Change and Sites, Fig. 1 Pacific regional sea-level history, relative to major cultural periods and events

(also known as the Medieval Warm Period or the Medieval Climate Anomaly), followed by a transition of the "A.D. 1300 Event" at A.D. 1250–1350, leading into a lowering of sea level during the Little Ice Age (LIA) at A.D. 1350–1800 (Nunn 2007). Currently, sea level has been rising for some decades in parallel with global warming, threatening coastal landforms, water resources, food productivity, and human populations worldwide. The current conditions may be viewed as the most recent part of continual sea-level rise since A.D. 1800, accelerated as a result of anthropogenic climate change.

From this long-term and material-based perspective of how people have coped with changing sea level, practical lessons can be leveraged into preparing for the effects of currently rising sea levels globally. The Pacific Islands have been at the forefront of these concerns, given the fact that many island environments and ecosystems are especially sensitive to minor changes in sea level. In the past as at present, island communities have been among the first in the world to be affected by changing conditions of coastal ecosystems, water tables, and other dynamics of their inhabited environments.

Key Issues/Current Debates/Future Directions/Examples

The demonstrated Pacific regional sea-level history supplies a baseline for assessing possible correlations with the cultural behaviors as chronicled in archaeological records. For instance, how did the mid-Holocene highstand influence the choice of where people first settled in the remote-distance Pacific Islands at 1500–1000 B.C., and then how did the subsequent sea-level drawdown affect life in the Pacific thereafter? Similar questions can be asked about the effects of higher and lower sea level during other time periods, such as the LCO and the transition to the LIA.

How Did Sea Level Affect First Island Settlement at 1500–1000 B.C.?

When people first moved to live in the remote-distance islands of the Pacific, about 1500–1000 B.C., sea level and coastal ecologies were generally stable and productive. This stability was due to the prevalence of the mid-Holocene sea-level highstand since 3000 B.C., wherein coral reefs and other coastal habitats had become well established for several successive centuries. In this scenario, the first settlers found truly pristine coastal ecosystems that had been healthy and productive for a millennium or longer.

Among the many favorable coastal settings at 1500–1000 B.C., people selected only certain of those paleo-seashore niches for their initial habitations (Carson 2016:133–168; Nunn and Heorake 2009). Residential sites have been documented directly at the ancient shorelines cross-regionally, for instance, as illustrated in the Mariana Islands and Fiji (Fig. 2). The settlers targeted the places where they could harvest abundant *Anadara* sp. shellfish that lived in mangroves, seagrass beds, or similar shallow-water habitats. They recruited other shellfish taxa from

Central Pacific Islands: Sea-Level Change and Sites, Fig. 2 Examples of the paleo-seashore settings of initial Remote Oceanic habitations of 1500–1000 B.C., as compared to modern conditions, shown in cases of the Mariana Islands (based on Carson 2016) and Fiji (based on Nunn and Heorake 2009)

nearby habitats, for example, seeking giant clams in nearshore zones and gathering varied limpets, sea urchins, and chitons in intertidal rocky exposures. Access to freshwater supplies would have been a priority as well, ideally from streams but sometimes found in coastal seeps just above sea level.

The selections of near-shoreline zones, access to shallow-water shellfish habitats, and freshwater sources all had depended on the position of mid-Holocene sea level at 1.5–2 m higher than today's conditions. In this way, sea level influenced how people first inhabited Remote Oceania, in a highly visible manner when considering the intrinsic roles of coastlines in small and remote islands. Similarly, any change in sea level could alter the ability of people to inhabit their preferred founding sites.

How Did Communities Respond to Sea-Level Drawdown After 1000 B.C.?

With the drawdown of sea level proceeding after the mid-Holocene highstand, many of the inhabited paleo-shoreline niches were reconfigured physically, thus forcing people to abandon these areas, as a critical threshold of sustainability was breached about 500 B.C. across the tropical Pacific. The falling sea level directly resulted in the decline or even total loss of the landforms, coral reefs, shellfish habitats, and other resources that had sustained the first island inhabitants. Sea-level drawdown was responsible for the loss of nearshore habitats supporting certain shellfish such as *Anadara* sp. clams, yet those effects were compounded by human-caused impacts of shellfish harvesting, in total creating nearshore resource depression (Carson 2016: 97–99). Further harvesting or overharvesting impacts have been documented in the case of the extirpation of one variety of giant clam (*Hippopus hippopus*) within the first few centuries of cultural settlement in Fiji (Seeto et al. 2012), as well as in the localized depopulations of rock-clinging taxa (limpets, sea urchins, and chitons) within the first few generations of coastal residence in the Mariana Islands (Carson 2016: 97–99).

While the paleo-seashore niches of the mid-Holocene highstand were disappearing, people needed to shift their focus to live in other landform contexts and to use different resource habitats. The sea-level drawdown thus introduced a degree of instability in fundamental subsistence supplies of coastal zones, forcing people to rely more on land-based resources from forests and domesticated foods that could overcome the new conditions of coastal instability. Options became available to inhabit elongate beach ridges and berms that had emerged in stranded positions above the lowered sea level, but the associated coral reefs and shellfish habitats could not offer the same prospects of productivity that had underwritten the sustainability of previous centuries of coastal settlement.

The records of nearshore resource depression, a shift in settlement location, and adjustment of subsistence economy coincided with the termination of cultural traditions of the most distinctive artifacts that had defined the earliest settlement sites. Most visible was the demise of dentate-stamped and other finely decorated potteries by 500 B.C., while certain forms of shell beads, bands, discs, circlets, and pendants disappeared as well in some island groups (Nunn and Carson 2015).

Given the simultaneous cross-regional correlation of so many aspects of changing physical environment and cultural behavior around 500 B.C., a principal cross-regional driving mechanism must be acknowledged as having affected all of the different areas of the inhabited Pacific. Depending on the perspective of analysis, the key factor could be viewed as the change in climate that triggered sea-level drawdown, as the lowering of sea level itself, as the transforming coastal ecology caused by sea-level change, or even as the social cognition of the changing environment. In any case, profound restructuring occurred in social and ecological contexts across much of the western Pacific by 500 B.C.

How Did Sea Level Influence the Habitability of Low-Lying Atolls After A.D. 100?

After the mid-Holocene highstand, sea-level drawdown exposed ever more low-lying coastal landforms, and eventually many small atolls such as in Micronesia became habitable during the first

Central Pacific Islands: Sea-Level Change and Sites, Fig. 3 Habitability of the atolls of Micronesia, A.D. 1–500

few centuries A.D. (Fig. 3). In practical terms, the physical land of the atoll (reef) islands had emerged sufficiently above sea level to sustain land-based livelihoods and to support settlements. Equally importantly, the sea level had dropped to a position that allowed freshwater lenses to form within the land masses of these islands, specifically at absolute elevations where people could access non-saline pockets of brackish groundwater through shallow pits.

Most of the atoll landforms had emerged above sea level as early as A.D. 100, but cultural habitation was delayed until perhaps A.D. 500 in many cases, due to at least two factors (Dickinson 2003; Nunn 2016; Yamaguchi et al. 2009). First, the sea level in some cases still needed to fall further to create accessible freshwater lenses. Second, people did not necessarily seek to migrate to inhabit all available atolls immediately.

The initial habitability of the Micronesian atolls underscores the role of sea level in affecting life in the Pacific and generally in coastal areas of the world. A small degree of changed sea level in this case made an enormous part of the globe habitable for the first time, with long-lasting ramifications for larger social and ecological history.

How Did Sea Level Affect Island Cultures at A.D. 750–1250?

Compared to earlier centuries, the Little Climatic Optimum (LCO) of A.D. 750–1250 can be defined by up to 1 °C warmer global temperature and overall increased annual rainfall, but it also culminated in a slightly higher sea level by as much as 1 m in the Pacific. In terms of understanding cultural response, the conditions of the LCO were steady and predictable interannually, thus allowing many communities to develop in greater densities and with more formalized land-use practice, permanency of residential patterns, and increasingly complex economic and political systems.

During the LCO in the Pacific, a slightly higher sea level generated both positive and negative effects on different coastal landforms and ecosystems (Nunn 2007), yet societies cross-regionally benefitted overall from the interannual predictability of warmer and wetter conditions (Fig. 4). Throughout all of the inhabited islands of Pacific Oceania after A.D. 1000, groups developed highly formalized settlement structures, permanency of land-use patterns, at-house burial traditions linking lineages with defined units of land, and monumental expressions often literally fixed in stone. These formalized expressions emerged in locally specific signatures cross-regionally, additionally impressive when considering that the centuries of A.D. 1000–1300 witnessed the creation of a fully inhabited sea of islands, filling the tropical and subtropical Pacific at that time.

The records of the LCO in the Pacific illustrate the role of interannual predictability in allowing societies to flourish, regardless of how their coastal landforms and ecologies were altered

Central Pacific Islands: Sea-Level Change and Sites, Fig. 4 Examples of settlement and land-use patterns before and after A.D. 1300 in Kaua‘i, Hawaiian Islands (following Nunn et al. 2007)

through a slightly higher sea level during those centuries. Near the end of the LCO, higher sea level potentially rendered some of the lowest elevations of coastal zones uninhabitable or unsuitable for large groups, because of flooding, erosion, and salinization. The same change in sea level meanwhile made other higher-elevation coastal zones more favorable for settlement. In all cases, island societies developed the formalized expressions and permanency of landscape relationships that characterized the region after A.D. 1000 and grew even more strongly established after A.D. 1300.

How Did the Sea Level Affect Island Cultures at A.D. 1350–1800?

Following the interannual predictability of the LCO, markedly unpredictable and volatile conditions came to characterize the Little Ice Age (LIA) at A.D. 1350–1800 in ways that threatened the previously established social systems (Nunn 2007), especially in the places where population densities had approached maximum carrying capacities (see Fig. 4). Changing sea level and coastal ecology were perhaps minor concerns during the LIA, while the more obvious concerns were cooler global temperatures and an increased frequency of punctuated events of storminess and drought. The LIA involved a lowering of sea level as compared to the prior case during the LCO, with direct effects on coastal communities of the Pacific, further complicated by tidal surges during storm events.

The LIA in itself was not an impossible situation, but rather the change from LCO to LIA conditions posed a challenge for many societies, dislodging them from their traditional lifeways and often leading to increased intergroup hostility or other forms of societal collapse (Nunn 2000). Particularly distressing was the inability of many island communities to maintain a sufficiently high level of food productivity in densely populated lands, for example, as documented in many Polynesian groups that had approached the limits of what the island ecosystems could provide. Especially visible in East Polynesia, populations expanded into marginal dry and upland environments by A.D. 1400. Intensive irrigation systems, dryland mound complexes, and artificial fishponds characterized most East Polynesian landscapes of A.D. 1400–1600, along with increased frequency of warfare, the use of refuge and fortification sites, and overall intergroup competition.

The LIA was a stressful time in the Pacific as elsewhere in the world, but it was managed without disastrous outcomes by most island societies. In the places where land-use systems were more generalized with forest management and informal horticulture, for instance, in most of Micronesia, people were equipped to withstand repeated storminess, drought, and other stressful events. These groups did not invest in the specialized and high-density food production systems that were seen most prominently in East Polynesia, but rather they continued to engage in low-density and generalized systems that already had proven useful for long-term survival in "typhoon alley." By comparison, the high-density systems such as in East Polynesia were overspecialized and therefore unsustainable for dense populations during stressful periods as occurred during the LIA.

What Are the Implications for Sea Level Affecting Environments and Societies in the Pacific and Globally?

This research has revealed cross-regional consistencies in how people coped successfully or unsuccessfully with changing sea level. The most long-term sustainable livelihood systems have tended to involve less formalized and instead generalized strategies of subsistence and land-use patterns, thus allowing the ability to withstand a degree of change in the inhabited environment both socially and ecologically. Whenever people relied on maximum usage of narrowly defined resource niches to support their growing populations, inevitably their descendant generations faced a crisis of not being able to sustain those strategies. At least a few instances have been chronicled in the cross-regional archaeological records, as seen with the post-highstand sea-level drawdown after 1000 B.C. and again with the transition from LCO to LIA conditions after A.D. 1300.

The exigency of a crisis in each case depended on the extent to which a community relied on the specific conditions of landforms or resource habitats that underwent substantive transformation. For example, cultural traditions based on narrowly defined paleo-seashore niches began to weaken after 1000 B.C. and could no longer be sustained by 500 B.C., such that the surviving generations of communities needed to develop significantly different material cultures, land-use patterns, and ways of interacting with their inhabited environments. Another radical change occurred for the societies that had developed highly formalized settlements, permanency of land-use patterns, and vastly increased population densities during optimal conditions of A.D. 1000–1300, eventually forced to transform or else to collapse when faced with the extended stress of less favorable climates of A.D. 1300–1850.

Lessons about coping with changing sea level are instructive while the world is facing a new challenge of global warming, rising sea level, and myriad attendant effects (Nunn 2013). These concerns are especially serious in areas of high-density populations, often situated in coastal areas that are most vulnerable to the erosion of seashores and salinization of water tables. Already, some Pacific atolls are losing their ability to support their populations, forcing their inhabitants to develop different subsistence practices, resource-use systems, and ways of living in their changing world.

[3]Institute of Archaeology, Research Centre for the Humanities, Hungarian Academy of Sciences, Budapest, Hungary

Introduction

This entry deals with the historical archaeology of the Eastern fringe of the Western Christian cultural area from the early Middle Ages onward, covering especially the three kingdoms of Bohemia, Poland, and Hungary and their dependencies. In general, the historical archaeology of Central–Eastern Europe (CEE) follows the current direction of Western European research with respect to methods and conceptualization. There are, however, some dissimilarities. These mainly relate to the historical geopolitical situation of CEE which gave rise to specific discontinuities and interferences by different cultural, religious, and ideological forces and which often left distinct archaeological evidence.

Definition

In CEE, historical archaeology is perceived as the part of general archaeology that studies society on the basis of material remains from the periods for which numerous written sources are available. In principle, it therefore includes the archaeology of the medieval and modern periods. In individual national archaeologies, however, periodization varies depending on specific historical developments. Accordingly, this entry has a wide overall chronological span, but for individual areas the range is quite variable. Thus, for Hungary historical archaeology covers the period from c. CE 1000 to 1800, whereas for the Czech Republic and Slovakia, the perspective is narrower, spanning only the late medieval and modern periods (CE 1450–1950). In Poland, although some scholars have begun to argue that historical archaeology spans roughly the same date range as used by their Hungarian colleagues (Kajzer 1996: 16–23), practically speaking, both in research agendas and academic study programs, the term "historical archaeology" is commonly attributed to the late medieval and modern periods (c. CE 1250–1945), which is why this narrower range is the one adopted here for this territory.

The concept of "historical archaeology," because it encompasses the traditional periods of historical and archaeological concern, is ideally suited to research the transitional periods between them, namely, between the early and high/late medieval (see Piekalski 2001; Klápště 2012,

2016), medieval and modern (e.g., Piekalski and Wachowski 2009), and early modern (preindustrial) and present (modern) periods. Moreover, the concept and concerns of historical archaeology in CEE overlap with both socioeconomic history and cultural anthropology (ethnology), as well as those of other disciplinary fields including historical anthropology, history of art and architecture, historical geography, history of science and technology, and legal studies (in connection with both forensic archaeology and the archaeology of material remains of past jurisdiction). The survey and documentary techniques used in historical archaeology are also closely related to those used in various branches of geography and biology (Krajíc 2007). The need for multidisciplinarity in historical archaeology is thus beyond doubt. The main methodological question is, however, how to combine the diverse information provided by different yet complementary groups of sources in order to gain new insights into the past society, rather than simply using archaeology to illustrate or repeat the narratives elaborated by historians.

In terms of the dissemination of research results, there are several journals and periodicals devoted to the archaeology of the Late Middle Ages and the (early) modern period covering CEE. For the Czech Republic and Slovakia, the key ones are as follows: *Studies in Post-Medieval Archaeology* (in English, a new series, published every 2 years since 2007), the journal *Archaeologia Historica* (published since 1976), and *Studia Archaeologica Slovaca Mediaevalia* (published irregularly since 1998). In Poland, the most important serial publication is *Archaeologia Historica Polona*; papers of likely relevance to CEE historical archaeology also appear frequently in *Kwartalnik Historii Kultury Materialnej* and in periodicals or serial editions devoted either to particular cities and regions (while popularizing approaches may be also found in *Z Otchrizing appr* and *Archeologia app*). In this regard, *Wratislavia Antiqua*, edited in Wrocław, is especially worth mentioning, while articles on the Hanseatic towns on the Baltic coast may be found either in local periodicals, printed in Elbląg, Gdańsk, and Kołobrzeg, or, in German, in *Lübecker Kolloquien zur Stadtarchäologie im Hanseraum*. Other publications concern particular themes or problems (e.g., *Funeralia Lednickie*, focusing on burial customs). In Hungary, there is a lack of journals dedicated specifically to the Late Middle Ages and the early modern period, but many articles and shorter reports can be found in several well-known and long-established journals like *Archaeologiai Értesítő* (Archaeological Bulletin published continuously since 1968) or *Acta Archaeologica Academiae Scientiarum Hungaricae* (published since 1950).

Historical Background

Through a large part of its medieval and early modern history, CEE was a contact zone between Western (Roman Catholic and Protestant) Christendom and the Orthodox and Muslim worlds. It developed in the cultural framework of Western Christian culture but against a strong local background (which leads to a variety of local attempts to adopt – and adapt – Western standards), owing to a very close contact with its Eastern and Southern neighbors where either Orthodox Christianity or Islam typically prevailed. Economically, the Northern part was linked to the Baltic sphere, and along with that it was gradually integrated into the strongly interconnected European economy and long-distance trade networks (1200–1800).

In the later Middle Ages, CEE encompassed the territories of three kingdoms (Bohemia, Poland, and Hungary) and the state of the Teutonic Order (Fig. 1). In the fifteenth to sixteenth centuries, Poland merged with the Grand Duchy of Lithuania into a unique Commonwealth (which also included the Ruthenian territories of present-day Belarus and Ukraine), whereas Bohemia and Hungary were integrated into the Habsburg Monarchy, facing the expansive Ottoman Empire. Central parts of Hungary were also conquered by the Ottomans, and the Eastern third of the medieval Hungarian monarchy, called Transylvania, became a duchy with a special vassal status within

Central–Eastern Europe: Historical Archaeology, Fig. 1 Central–Eastern Europe in the Late Middle Ages. The thick line highlights the conventional (academic) border between Central–Eastern and Central–Western Europe. Today, CEE is perceived as the area encompassing Poland, the Czech Republic, Hungary, and the Slovak Republic. On the other hand, Central–Western Europe then consists of Germany, Austria, and Switzerland. Fluid borders remain between Southeastern (North Balkans) and Eastern Europe. (After Myśliwsky 2012, Fig. 8.1, slightly modified)

the Ottoman Empire. The state of the Teutonic Order was partly incorporated into Poland, whereas the rest of it developed into the Duchy and later Kingdom of Prussia. In the eighteenth and nineteenth centuries, CEE was dominated by the expansion of the Habsburg Monarchy, Prussia, and Russia. In the twentieth century, the region was subject to strong pressure and cultural influence from both Germany and the Soviet Union.

Key Issues/Current Debates

Historical archaeology in CEE has expanded in the last 25 years, although its first foundations were laid much earlier (Smetánka and Žegklitz 1990). This growth is largely a consequence of the gradual and ever-growing acceptance – both among relevant authorities and archaeologists themselves – of late medieval and modern

material relics as subjects of legitimate research and of equal merit to pre- and protohistoric archaeological sites and artifacts. Historical archaeology is especially gaining in importance in the field of impact assessment surveys and rescue excavations accompanying new building development (which have been in all respective states legally integrated into the processes of acquiring building permissions). There are also research-driven studies in such fields as rural settlement (at least in Bohemia, Slovakia, and Hungary), battlefield archaeology, forensic and legal archaeology (especially in Poland), and scholarly elaboration of some aspects of the material culture of these periods, rather than simply salvage exercises. Nonetheless, this close interdependence between historical archaeology and rescue excavations causes discrepancies in certain research areas. For example, because historical archaeology is so closely associated with predevelopment impact assessment and mitigation, the densest concentration of field research has been in the historical core areas of cities where architectural and archaeological heritage has been threatened by new building development (notably Brno, Elbląg, Gdańsk, Prague, and Wrocław). The same level of research into the historical archaeology outside the major cities has not been attained, however, and only in the last 25 years have attempts been made to improve the legal and practical status of late medieval and modern archaeological sites in the countryside so as to accord them the same level of protection as given to monuments from earlier periods. This has mostly been accomplished by including archaeological surveys and excavations in the more general structure of heritage protection and by creating heritage protection areas, as has been attempted in Poland and the Czech Republic.

The broad spectrum of topics potentially reflected in the archaeological materials from historical periods allows for a variety of possible narratives to describe them. To accommodate this, in the following sections, current key research questions concerning the historical archaeology of CEE are also related to the grand concepts of European historiography and presented in chronological order.

The Medieval Transformation (1100–1350)

Archaeology has substantially contributed to the creation of the dominant historical narrative of the medieval transformation of CEE (Klápště 2012, 2016). This model explains the historical processes of the eleventh to fourteenth centuries as a gradual cultural, social, and economic integration of Central–Eastern Europe into a wider Latin Europe. In the study of the transformation processes, which included, e.g., the commercialization of the economy and the structures of power, both the idea of a development convergent with Western European phenomena and the hypothesis of cultural diffusion of technologies and social patterns figure highly. In this regard, the contribution of archaeological research has mainly concerned the spatial spread of the changes, their relations to previous socioeconomic and cultural patterns, the diversity of local histories, and various local solutions to regionally common challenges (e.g., Piekalski 2001).

Late Medieval Archaeology: The Transition from the Medieval to the Postmedieval World (1350–1550)

For this time period, archaeological interest has focused on researching continuities and changes in the urban milieu, rural settlement patterns, landscape, and technologies (cf. Scholkmann 2009; Carver and Klápště 2011; Klápště 2016). CEE development in the fifteenth to sixteenth centuries is typically portrayed as a gradual accumulation of diverse changes and responses prompted by developments in the previous period. However, the rate and intensity of the development were not the same across all parts of CEE, which emerged from this period as one subdivided into numerous differently functioning but interconnected socioeconomic regions. Some of these headed toward proto-industrialization and commercialization, while in others it was as if time stood still. In the fifteenth to sixteenth centuries, the development of Hungary, as a borderland on the margins of the Ottoman Empire, with large parts occupied by the Ottomans, was again special, characterized by the emergence of market towns involved in cross-border trade with their Islamic neighbors.

Postmedieval Archaeology: Differentiation in the Early Modern Period (1500–1800)

In the early modern period, the individual parts of CEE underwent very diverse developments. The historical processes in the Western and Northern parts of CEE are traditionally conceptualized within the "grand historical narratives" of the early modern periods, such as the origin of modern society, industrialization, and commercialization. However, archaeological research along with micro-history and cultural anthropology creates parallel and less universalizing views of this period. Most parts of the Polish–Lithuanian Commonwealth, for example, did not head toward proto-industrialization. On the contrary, the demand for grain in Western Europe in the fifteenth to sixteenth centuries led to the development hereof extensive agrarian production and specialized long-distance trade. In the Southeast of CEE, the trajectory of change was influenced by the long-term expansion of the Ottoman Empire (c. 1300–1700). This area was characterized by military conflicts and instability in the cultural, ethnic–religious, and socioeconomic spheres. The process of early industrialization in Hungary was significantly affected by this unfavorable situation. The long-lasting Ottoman occupation of the Southern parts and the constant fear of the threat of invasion by the Ottoman Empire, combined with frequent clashes between the nobles and the monarchs, also meant that the area of present-day Slovakia and a large part of Hungary were focused almost exclusively on agriculture, with the exception of prosperous mining towns and settlements.

Modern Industrial Era (1750–Present)

The archaeological database for this period is enormously extensive and very rich in potential (Matoušek 2011, 2015; Vařeka 2013). Nevertheless, historical archaeology of the industrial era in CEE continues to be regarded as a peripheral concern and often has been left to historical geographers, historians of science and technology, and cultural anthropologists to research. This is now changing, however, with emerging interests in the historical archaeology of this era from the perspective of (1) forensic archaeology and the archaeology of conflict, (2) the archaeology of totalitarian regimes and political crimes, (3) the archaeology of leisure (Vařeka and Symonds 2012), and (4) the archaeology of abandoned landscapes and depopulated frontier zones, such as along the Iron Curtain separating the Soviet Union sphere in Europe until 1989.

Thematic Approaches

Another way of approaching the historical archaeology of CEE, which is popular with many researchers especially those working on late medieval and modern materials, tries to dispense with the grand historical narratives and focuses instead on traditional, "anthropologically oriented" classification of finds and their functional contexts while also relating these schemes to local ethnography and the history of material culture (Smetánka and Žegklitz 1990; Krajíc 2007; Klápště 2016; Matoušek 2015; special issue of the journal *Archaeologia Historica 2017*). The following paragraphs outline a selection of these.

Material Culture Studies

The amount of archaeological evidence concerning the last few centuries has recently increased exponentially. However, there are fundamental differences in terms of their information potential between the assemblages of artifacts concerning late medieval and modern society, and only some of them can be associated with a particular social context. In some cases, the artifacts both in their place of production and in their place of consumption can be studied simultaneously, as best illustrated by a recent study of the pottery workshop of Adam Špaček in Prague (1532–1571) and the distribution of its tile production in different social milieus (Žegklitz et al. 2009). This exposed the ambivalent character of some artifact types such as relief stove tiles and connected archaeology and art history. The former helps provide information on both the provenance and the social context of the users of these tiles, while their meaning and aesthetic significance are amenable to interpretation using the methods and analytical frameworks of art history (Fig. 2; Žegklitz 2012), including questions of symbolic

Central–Eastern Europe: Historical Archaeology, Fig. 2 Artifacts between archaeology and art history. Images of the priest John Hus (Jan Hus, ca 1369–1415) burnt at the stake for heresy against the doctrines of the Catholic Church, after which he was considered by Luther and other early modern church reformers as one of their predecessors. (**a**) A stove tile, Prague Castle. (**b**) A semifinished stove tile, Prague, the pottery workshop of Adam Špaček (1532–1571). (**c**) A 1530s medal by Hieronymus Dietrich. (**d**) A woodcut by Erhard Schoen, c. 1530. (After Žegklitz 2012, Fig. 57)

culture and heraldry (e.g., stove tiles from the Wawel Castle in Cracow).

The enormous quantity of ceramic and glass evidence has also been studied by archaeologists, historians, and cultural anthropologists, and their complementary research frameworks often intermingle. Thus, some researchers have tend to use this material to explore the beginnings of modern consumer society with an emphasis on changes in well-being and easier access to goods; others have focused more on the impacts of technological innovations and the beginnings of new patterns of production, distribution, and consumption; and others still have explored changes in the direction, scale, and extent of long-distance trade and town-market exchange circles (Fig. 3; cf. Gaimster 2009). Only latterly have the transformations in the local ceramic wares become a topic of research and publication, with analyses focusing on the investigation of local craftsmen (Benkö and Kovács 2010). In Hungary, the first phase of research of this kind was marked by the investigation of prestigious ceramic wares, to a large part produced by Anabaptists (Fig. 4; with the local name Habans), and by the analysis of multicolored Majolica ware,

Central–Eastern Europe: Historical Archaeology, Fig. 3 Lump of lead (size 88.7 × 81 × 19 cm, weight 11 cwt = ca 570 kg) excavated in 2006 near to the remains of the Great Scales in the main Market Square, Cracow, with imprints of official seals from the fourteenth century, the only existing find of this sort in the world. (After Buśko et al. 2009, Fig. 4)

e.g., Iznik ware, derived from the Ottoman Empire. Anabaptists (Habans) were a radical religious sect within the reform Christian movement who lived under the protection of the Protestant lords in South Moravia and Hungary. Their closed communities excelled in various branches of specialized agriculture as well as craft production. At the end of the sixteenth century, Anabaptist potters in Moravia and Hungary introduced modern Italian or Western European production technologies, such as tin-glazed pottery (faience).

Religious Culture as Reflected in Archaeological Evidence

Important research areas between the Late Middle Ages and the early modern period are the ideology and religiosity of these periods, in particular the

Central–Eastern Europe: Historical Archaeology, Fig. 4 The motifs of Anabaptist ceramics in Moravia (ca 1600) and the excavated foundations of a pottery kiln (Strachotín, Ostrožská Nová Ves). (After Pajer 2001, book cover, příl. VIII–IX; Pajer 2007, Fig. 3)

diversity of popular responses to changes in everyday life driven by religious movements and phenomena such as Hussitism and the Reformation. In general, the research deals with the artifacts as the means of maintaining and representing social, ideological, and religious identity in internally ambivalent societies. Unique insight into the religious culture of the Late Middle Ages and the early modern period may be obtained through studying artifacts of private devotion, such as the miniature crosses found in graves or pilgrim utensils, including badges, ampoules, and water flasks (e.g., the find of 25 late medieval ceramic pilgrim flasks from Trzebnica, related to the local saint, Princess of Silesia, Jadwiga/Hedwig). As a specific case of studying religious life, research on particular monastic communities is important, especially as this offers insight into their everyday life, economic situation, and the standards of living of their members (e.g., Łekno or Strzelno in Poland, the Capuchin monastery on Republic Square in Prague).

The influence of prevailing religious culture may be approached by archaeologists with special precision through research on cemeteries. There are unique opportunities for comparing religious customs and beliefs in the centers with a high degree of social stratification and confessional diversity (e.g., the cities of Wrocław, Brno, and Prague, where Catholic [including those of monastic communities], Protestant, and Jewish cemeteries have been excavated). An example offering considerable scope for the analysis of religious self-determination as well as of the

social stratification is provided by the remains of late medieval and early modern clothes recovered from excavations at the former monastery of Boldva in Hungary which was also used by Protestant lords. Micro-historical insights can also been gleaned from uniconfessional village cemeteries, such as that in Maniowy in Lesser Poland, as the data recovered tends to concern the influence of more localized beliefs and customs of past societies. A special case of inhumations is those of "alienates," the men isolated from the "normal" majority of the buried populace because of their unusual physical or psychic characteristics (Unger 2006; Duma 2010, 2015).

As far as the development of Christian burial rite in the thirteenth to eighteenth centuries is concerned, the archaeologically studied differences cannot be directly related to such religious changes as the Reformation in the sixteenth century. The influence of general cultural innovations, including the introduction and rise of Baroque religiousness, was stronger, essentially affecting the grave furnishings in both the Protestant and Catholic areas (Králíková 2007; Scholkmann et al. 2009).

Castles, Residences, and Manors

The problems of royal and noble seats – both fortified and purely residential – and castles are being studied not only within all three pre-industrial periods of the four periods discussed above but also between them, showing long-term changes and developments. Thanks to methodical excavations of noble residences of the Late Middle Ages (such as Plemięta and Siedlątków in Poland, the late medieval Rokštejn and Lelekovice in Moravia, and the late medieval layers of the castles of Nagykanizsa, Salgó, and Fűzér in Hungary), extremely interesting assemblages of artifacts have become known (which has made it possible, e.g., to reconstruct personal armories of that period – for an overview of such sites in Poland, see Marciniak-Kajzer 2011, concerning Hungary, Benkö and Kovács 2010) (Fig. 5). Thanks to some excavations of noble seats (e.g., Nowe Miasto and Zduny in Major Poland), such long-term developments, including the changes in the building techniques and architectural forms as well as the mobile inventories, are traceable from the thirteenth/fourteenth to the seventeenth centuries.

Central–Eastern Europe: Historical Archaeology, Fig. 5 Metal parts of hunting weapons discovered in the well at Castle Chojnik, Lower Silesia, Poland, sixteenth to seventeenth centuries. (After Marek 2008, Fig. 2)

Castles are also being studied by archaeologists along with historians and architects in terms of their various functions (see generally Kajzer 1996: 113–155). As the castles reflected social and cultural changes, some of them were developing (e.g., being provided with modern fortifications), while others were abandoned or replaced with newly built palaces and other forms of elite residences. Royal residences such as Prague Castle in Bohemia, Buda Castle in Hungary, Bratislava Castle in Slovakia, and the Wawel Castle in Cracow in Poland, as well as other defensive and residential structures of special significance (e.g., monastic castles of the Teutonic Order), have been the focus of much long-term research owing to the great interest among both researchers and the broader public in such spaces.

The Standards of Living in the Late Medieval and Modern Periods

Archaeological research has provided numerous testimonies of positive changes in the home comfort of late medieval and early modern townsmen, noblemen, and peasants depending on their social status and economic situation. Progress in the well-being of communities is mirrored in the technical infrastructure of urban and rural settlements (wells, paved roads, water and sewage management devices, water mills, etc.). However, the topics for discussion are (1) the chronology, geography, and detailed topography of such changes and (2) whether the development was general or reflected an increase of internal socioeconomic inequality. In this regard, urban and graveyard archaeology thus far has provided the best opportunities for studying subsistence change and the impacts of epidemics. Archaeology even makes it possible to study people's prophylactic activities (e.g., through finds of bottles in which mineral water was carried).

Landscape Archaeology

For the Western parts of CEE, there has been systematic research on the changes and continuity of settlement patterns and land use strategies, rural settlement abandonment, and the rise of small towns. Much of this has tended to support the notion of a late medieval crisis, although current research projects are also exploring the late medieval origin of the drivers of change. Increasingly, landscape archaeology of the early modern period is focused on the growing socioeconomic diversity at regional and macro-regional scales. The landscape evidence includes specific proof of both the early modern industrialization of mountainous regions (Klír 2011) and the complementary agrarian change in the lowlands and the commercialization of agriculture. In cooperation with cultural anthropologists, landscape archaeologists have begun to study human activities and social groups that are poorly represented in written sources, such as the activities of groups like charcoal burners in the forest areas. Nondestructive methods and GIS applications are also gaining in importance as is the degree of integration of various types of sources (huge inflow of new data has been recently provided by ALS). Considerable scope for new research is also offered by those areas (frontier zones, former military areas, so-called interior periphery areas) which were populated and often intensively used for agriculture until the middle of the twentieth century but are currently depopulated and forested (Fig. 6).

The Archaeology of War and Warfare

A very attractive part of the archaeological evidence of the Late Middle Ages and the early modern period is the novel information it can provide concerning the various wars and conflicts connected with the rise of modern nation-states in the region (Fig. 7; cf. Matoušek 2006). In particular, because CEE was a buffer zone, these data offer considerable scope to compare different (especially Western and Eastern) combat equipment and battle strategies. Both particular battlefields (e.g., the battlefields of Beresteczko in Ukraine, Třebel in Bohemia, and Mohács in Hungary) and their associated burial sites (e.g., on the field of the Battle of Grunwald in 1410) are being researched. Both provide insight into the techniques of warfare. The archaeology of warfare is not limited to campaigns led on land, and research is also being undertaken on sea-battle sites (e.g., underwater research of the wreck of the Swedish

Central–Eastern Europe: Historical Archaeology, Fig. 6 Example of the archaeology of an abandoned landscape in the CEE – Rozpakov, Central Bohemia, 2011: (**a**) a still-standing Baroque mill, (**b**) the perimeter wall of a defunct millrace, (**c**) dilapidated outbuildings. (Photos by D. Vodáková)

flagship Solen in Gdańsk Bay, Poland). In Hungary, a special branch of investigation focuses on the early modern (sixteenth to seventeenth century) fortifications on the Hungarian–Ottoman border with a special accent on newly erected forts. Work at one of them, Bajcsa/Weitschawar in the vicinity of the modern town of Nagykanizsa, built with finances from Steiermark, has become something of a benchmark, not only because of the large scale of excavations carried out but also because the fort is especially well preserved having been abandoned shortly after its erection (Benkö and Kovács 2010).

The Documentation of Politically Motivated Nazi and Soviet Crimes

A very specific branch of the archaeology of CEE is the research and documentation focused on the sites related to totalitarian political crimes. These are, namely, the remains of Nazi and Soviet concentration, forced-labor and prisoner-of-war camps, as well as places where the people

Central–Eastern Europe: Historical Archaeology, Fig. 7 The battlefield of the 30 Years' War beneath Třebel, Western Bohemia: (**a**) engraving in the Theatrum Europaeum VI depicting the battlefield on 19th of August 1647 showing the Swedish position to the left (*West*) and the Imperial Army's position on the right (*East*), (**b**) relicts of an archaeologically examined redoubt built by the Imperial Army (marked by the *arrow* on **a**), (**c**) an experimental reconstruction of the same redoubt. (After Matoušek 2006, obr. 4, 38, tab. 6)

prosecuted by these regimes were executed or buried. This branch of research is especially developed in Poland, where it fits well into the institutional framework of the respective state offices (ROPWiM and IPN) and meets the expectations of the society – especially the relatives of the murdered persons, as archaeological excavation of mass graves often makes it possible to identify the victims (Figs. 8 and 9; e.g., Charków and Bykownia, Ukraine, or Bełżec camp, Poland; see Kola 2000, 2005). In Hungary, only one branch of these excavations has been executed as yet: the exhumation of the victims of the terror after the Revolution in 1956, with a

special regard to the excavation of Imre Nagy and other leaders of this anti-Soviet movement.

Historical Medieval Archaeology in Southeastern Europe

Aims

The term "historical archaeology" has a separate and wider meaning in Southeastern Europe (SEE), especially as archaeological research on the Late Middle Ages and early modern period has been virtually nonexistent apart from a few studies in Bulgaria. Only excavations within churches are carried out frequently, and generally such work has been treated as being part of art history not archaeology. This is because in all of the SEE countries, the period of Ottoman rule is still seen as one of total decline and contrasted with the "glorious" Middle Ages. Hence in this part of Europe, the term "historical archaeology" is really a synonym for "medieval archaeology" and also the "nationalist archaeologies" established in the nineteenth century. These typically used the analysis of the medieval material culture of given contemporary ethnic groups to underline the glory of their medieval past thereby lending support to arguments for the achievement of modern political goals.

SEE before 1918 was inhabited by numerous ethnic groups lacking formal affiliation with specific independent states. Because of this, "historical archaeology" was used to outline the territorial borders favored by a given nationalist movement. In this sense, "historical archaeology" shared the same role in "proving" the prior existence of a national identity as historiography, often taking over its nationalist narrative, vocabulary, and delimitation of appropriate research questions. The Christian clergy also played a crucial role in the formation of nationalist archaeology in the region especially within groups of the Orthodox faith: Serbs, Romanians, and Bulgarians. This was because a significant proportion of the medieval written records for Central and Eastern Hungary, Croatia, Bosnia, Serbia, Bulgaria, Wallachia, Moldova, and the SEE territories of the Byzantine Empire were destroyed following the Ottoman conquest of the region in the fourteenth to fifteenth century and the clergy need to find other sources that might confirm their view of pre-Ottoman history.

The events of the twentieth century only partially changed the direction of research in the region. After World War I, archaeologist in the victorious countries (especially Serbia and Romania) exerted great efforts toward justifying their new borders with reference to the archaeological record. At the same time, countries on the losing side (e.g., Bulgaria) also used historical archaeology to create arguments in favor of the revision of these borders! After World War II, the Communist takeover in almost all of SEE resulted in the introduction of a new vocabulary aimed at undermining older narratives of national glory. However, the new narratives that were developed still emphasized national identities rather than those more characteristic of historical materialism (such as the rise of the proletariat). Even in Albania, the country with the most rigid Communist regime, after 1945 archaeologists continued to interpret their evidence in terms of a prevailing nationalist ideology.

New approaches eventually appeared in the last third of the twentieth century, shortly before the end of Soviet influence. These changes were marked by the development of interest in research questions dealing with everyday life and mentalities in the Middle Ages and the era of the Ottoman conquest. Historical archaeology could still be politically motivated, however, especially in the former Yugoslavia where multiple historical narratives were reformulated prior to the interethnic war of 1991–1994, with the goal of creating a climate for war. As part of this, numerous World War II mass graves were excavated, especially by Serbian authorities, in order to "prove" the genocidal tendencies of their opponents.

Chronological Framework

Today, the temporal range of what is considered to be "historical archaeology" still varies widely across SEE. In Albania and Romania, the concept has its greatest temporal depth largely because archaeology in these nations is still directed toward proving that Albanian and Romanian

ethnicities have formed the majority population since the Iron Age. The concept of continuity forms the central part of the historical narratives of these countries, regardless of the fact that until the Later Middle Ages, there is no firm evidence to support such a suggestion. The shortest time scale is used in Macedonia (=FYROM), where the rule of Tsar Samuil at the turn of the eleventh century is misinterpreted as the predecessor of the modern nation and state. In Slovenia, historical archaeology was tied to the period of the Duchy of Carantania in the eighth century especially prior to the 1970s, but nowadays also the later parts of the Middle Ages are analyzed. In Croatia, the period analyzed is that of the royal Trpimirović dynasty (eighth to eleventh century). In Bosnia, the main focus is placed on the period of the Kotromanić dynasty (thirteenth to fifteenth century), and in Serbia and Montenegro, it is the period of the Nemanjić dynasty (thirteenth to fifteenth century) that marks the start of historical archaeology. In Albania, the time scale for medieval archaeology is formed, aside from analysis of the Illyrians, by the short rule of Gjergj Kastrioti Skënderbeu (1444–1468). Generally, the nationally interpreted historical archaeology in this region is a style of scholarship that selectively focuses only on those shorter periods of the Middle Ages that are of national interest. Only in Bulgaria is historical archaeology treated more broadly, covering the periods of the two medieval Bulgarian states (seventh to tenth century and fifteenth to fourteenth century), although there is still a lack of interest in the intervening period of Byzantine rule.

Major Projects

The level of the transformation of a national archaeology into a "standard" medieval archaeology of the continental type can be measured by the level of attention devoted to themes and sites associated with low prestige, such as rural settlements and their inhabitants. This has yet to occur in SEE, and given the strong nationalist tendencies outlined above, it is perhaps inevitable that the main focus of historical archaeology in SEE has been on sites that could be interpreted as reflecting earlier national achievements and glory. These include early medieval cemeteries with rich grave goods, royal residencies, forts, and various church buildings. In the field of early medieval funerary archaeology, the main projects have been in Slovenia, Croatia, and Bulgaria (such as on the sites of Kranj and Ptuj in Slovenia, Knin–Biskupija and Nin in Croatia, and Novi Pazar in Bulgaria). The results from these have been integral to interpretations of the Köttlach culture and the cultures of the old Croats and of the old Bulgarians. Concerning early medieval residencies, large-scale excavations have been carried out mainly in Bulgaria – at Pliska and Veliki Preslav. Large-scale excavations of medieval forts have been conducted in almost all countries in the region and regularly at strongholds serving as royal or noble residences. These sites include Bled and Ljubljana (Slovenia), Medvedgrad and Bribir (Croatia), Bobovac and Kraljeva Sutjeska (Bulgaria/Hungary), Ras (Serbia), Prilep (FYROM), Veliko Tărnovo (Bulgaria), and Krujë (Albania). Finally, many medieval churches in SEE have been identified as sites of national interest and have been excavated. In these projects, the importance of the excavated remains was often overestimated so as to support a national narrative. Of broader interest is the early medieval sacral architecture of Croatia and Bulgaria, as well as the thirteenth- to fifteenth-century churches of Serbia, Kosovo, Macedonia, and Greece.

International Perspectives

From the viewpoint of an insider, CEE must be conceived simultaneously as a region in itself and as a transitional, buffer zone. It was not only an area which passed Western traditions eastward but also a very specific region which accepted cultural stimuli from the East (e.g., Oriental customs in clothing and military equipment). In one sense, CEE is very much a frontier zone, a place where Western trends and patterns end (and it is a matter of constant discussion where exactly and how they were adapted to local contexts) and where the Eastern ones did not yet begin. On the other hand, for each subperiod CEE must be conceived as responsive to

different networks of external relations. Thus, for instance, in the Late Middle Ages, CEE was part of the peripheral zone of the West-European core, along with other "fringe" areas (e.g., Germania Slavica, Scandinavia, the British Isles). In the industrial era, on the other hand, CEE was part of a different periphery along with other areas on the Northern and Eastern edges of Western civilization, such as the Baltic and Danubian areas.

Future Directions

Historical archaeology in CEE is a young and rapidly expanding subdiscipline. In terms of its theoretical framework, objectives, research topics, and publications, late medieval and post-medieval archaeology (1450–1800) is already relatively well established and is widely taught at university level. In contrast, the archaeology of the later modern and recent past (1800–present) is still evolving. Currently it is fragmented into a myriad of component topics, more often inspired by topical issues in cultural and social anthropology and history than by archaeological concerns. However, the level of popular interest in the archaeology of the more recent past has grown enormously, largely thanks to a general shift of interest away from earlier history (the Middle Ages, the early modern period) to the region's most recent history, and it is no mere coincidence that the archaeology of the modern period has developed chiefly at newly established universities and other centers of higher education. This shift in popular interest toward modern history, especially World War II, forces both archaeologists and heritage management authorities to cooperate with amateur groups attempting to explore the material remains of the recent past. The development of a suitable legal and practical framework for such cooperation is certainly one of the most important tasks for the future. South-eastern Europe is specific also in terms of this problem. As at the turn of the 1990s, various "historical arguments" were produced concerning the territory of the former Yugoslavia that created a climate of war and revenge. Special effort is now needed to reveal the untruthful nature of these narratives, especially those elements connected with nationalist-inspired interpretations of the region's historical archaeology.

Centre for Archaeological Sciences (Katholieke Universiteit Leuven)

Patrick Degryse
Centre for Archaeological Sciences, KU Leuven, Leuven, Belgium

Basic Information

The Katholieke Universiteit Leuven (K.U. Leuven, Belgium, http://www.kuleuven.be/english), founded in 1425, has a rich tradition of learning and research of almost six centuries. Among its most famous researchers are Vesalius, Rega, Erasmus, and Mercator. Fundamental research at the university is specifically profiled through the virtual disappearance of interdisciplinary boundaries. An example of this strategy in the past decades has been the cooperation between archaeological projects and several disciplines from the exact sciences. Especially the research unit on Eastern Mediterranean Archaeology, with the excavations at Turkish Sagalassos, had established an interdisciplinary approach, spanning more than 30 years. In the light of the increasing importance of such interdisciplinary research in all fields and areas of archaeology, it was decided in 2005 to create the *Centre for Archaeological Sciences* (*CAS*), 1 of only 12 excellence poles at the K.U. Leuven selected after international peer review. The main goal of this interdisciplinary center of excellence was to support K.U. Leuven and international archaeological research projects with an extensive and in-depth experience built up in the faculties of exact sciences, biomedical sciences, and engineering in Leuven. In 2010, it was decided to continue *CAS* as a center of excellence under the "program financing" scheme of the university. In this way, the center will certainly remain funded until 2017. A shift in focus was made from site-driven research to a more methodological approach to archaeological science. While the center was founded by Professor Marc Waelkens (2005–2010), the current director (as of 2010) is Professor Patrick Degryse.

Major Impact

CAS currently acts as a focal point for archaeological science research, to be made available to the international community, comprising several different specialities. In particular, prime research areas are palynology and paleobotany (including carpology), vertebrate and invertebrate archaeozoology, paleolandscape and climate reconstruction, remote sensing, human-environment interactions (integrating all of the aforementioned), physical anthropology (using stable isotopes, CT, and aDNA), organic (using residue and lipid analysis and aDNA) and inorganic (soil, clay, stone, etc.) raw material research and archaeological materials science, and archaeometry (ceramic, glass, metal, mortar, stone, etc. characterization through mineralogy, petrography, and geochemistry, including radiogenic isotopes). The center is composed of over 20 international postdocs and doctoral researchers in several disciplines of bio-, geo-, and medical sciences, supported by senior researchers from all the aforementioned faculties (www.archscience.be).

Centuriation and Roman Land Surveying (Republic Through Empire)

Marinella Pasquinucci
Dipartimento Civiltà e Forme del Sapere, University of Pisa, Pisa, Italy

Introduction

Centuriatio or *limitatio* was a Roman method of land delimitation and division by means of orthogonal and equidistant *limites* (literally, borders). Depending on the local geomorphology, these were roads and/or ditches and defined mostly square, less frequently rectangular, areas of fixed dimensions named *centuriae*; in many cases, each *centuria* was 200 *iugera* (50.4 ha) wide.

Centuriation accompanied Roman colonization and provided the new settlement with productive soil, proper infrastructure (roads, ditches, if necessary bridges), and a cadastral frame for allocating land to colonists (Fig. 1).

Centuriatio and land surveying are documented by Roman, late Roman, and medieval texts and also by archaeological evidence. The study is based on Roman, late Roman, and medieval texts and inscriptions; historical maps and scientific cartography; local geomorphology and paleogeography; archaeological survey and excavation; ancient surveying instruments; toponyms; remote sensing; geophysical surveys; computer-based analysis; and increasingly by GIS (geographic information systems).

The fundamental textual source is the *Corpus Agrimensorum Romanorum* (*CAR*), a collection of texts by different authors on several aspects of land surveying. The original compilation is dated to the fifth century CE, while other writings were added afterward (Campbell 2000: xxii; Toneatto 2010).

In the Mediterranean and Near Eastern worlds, the main principles of land division and allocation have very ancient origins, but the instruments, terminology, and peculiarities of Roman land surveying highlight the specific autonomy of the Roman procedure (Lewis 2001: 123).

Centuriatio/limitatio was applied from the late fourth century BCE, when Rome took over the Latin League and started founding colonies. It accompanied the whole history of Roman colonization, which consisted both of the foundation of new towns (*coloniae*) and the settling of individual colonists (*ager viritim divisus*: viritane settlement or viritane colony). In some areas, the territories of *municipia* or even smaller places came to be centuriated (Dilke 1971: 88, 221; Campbell 2000: 321–322). The *centuriatio* was constructed by land surveyors who first carefully explored the territory in order to choose the proper orientation of the centurial grid. Then, using their instruments (mainly the *groma*), they traced orthogonal *rigores* (straight lines) which were contextually fixed on the soil by stones or sticks and subsequently converted into *limites* (roads or ditches) by the colonists who worked under the supervision of the land surveyors and the magistrates appointed as commissioners for the new urban foundation. The two orthogonal *limites* intersecting at the central point of the centuriated area were named *kardo maximus* and *decumanus maximus*, according to their orientation: the former often ran north–south, the latter east–west. The other *limites* were then traced parallel to the first ones; they were called *kardines*/*cardines* and *decumani*/*decimani*.

In the final phase of the colonial foundation, colonists were assigned their plots by drawing

Centuriation and Roman Land Surveying (Republic Through Empire), Fig. 1 A colony and its centuriated landscape

lots. The surveyors initially registered the results on temporary tablets and finally on bronze or marble tablets which were carefully prepared and displayed to the public in the local archives. Copies were kept in the urban archives, showing that the procedure was centralized and strictly controlled by Rome and at the same time a relevant matter of public solicitude in local communities (Campbell 1996: 90). The operations described here usually required at least 3 years to complete (Dilke 1971: 35). Centuriation had a relevant role in enhancing the rural economy and defining the rural property.

Since centuriation conformed to the local geomorphology and hydrography, in most areas of the Roman world these land divisions persisted through Late Antiquity and the Middle Ages and still persist in many landscapes of the Roman world; it is very evident in southern Europe and North Africa (Campbell 1996: 75) (Fig. 2). In some countries, the surviving evidence is protected by local cultural heritage agencies as specific and fundamental historical/cultural landscapes.

Definition

The term *centuriatio* derives from *centuria* and this from *centum* (one hundred) since, according to ancient sources, its size originally corresponded to one hundred *heredia*. *Heredium* (hereditary parcel) was the amount of land allocated by Romulus to each Roman citizen, according to an anachronistic tradition of the late Republican (Gabba 1978). The term *limitatio* derives from *limes* (boundary, in agriculture a path or baulk; Dilke 1971: 87). The roads and/or ditches (*limites*) forming the centurial grid were called *kardines* or *cardines* (often oriented north–south) and *decumani* (later *decimani*, often oriented east–west).

The main ones, intersecting at right angles in the center of the centuriated area, were the *kardo maximus* and the *decumanus maximus*, abbreviated as KM and DM. *Kardo* (hinge) was used also of any pivot, axis, or pole (Dilke 1971: 87, 231). *Decumanus* derives from *decimus* (tenth): according to the sources (Siculus Flaccus 153 and 136 L; *Hyginus* 115 L), the term derived from the

Centuriation and Roman Land Surveying (Republic Through Empire), Fig. 2 Centuriated landscape of Modena (*Mutina*): an aerial view

number 10, since 10 *actus* of length were the sides of the squares forming an early land division called *agri quaestorii* (Dilke 1971: 88, 231–232).

Historical Background and Key Issues

Roman surveying theory and practice were closely intertwined with the Etruscan ones, on account of geographical proximity, as well as historical and cultural connections. They largely derived from the Greek experiences, which in turn descended from Egyptian, Mesopotamian (mainly Babylonian), and possibly Persian ones (Lewis 2001: 13–18, 115).

Although ancient traditions trace the main principles of land division and allocation to the origins of Rome, on the ground of evidence, centuriation originated in Italy at least in the late fourth century BCE (Lewis 2001: 122), when Rome took over the Latin League, becoming the main power in central Italy (338 BCE) and winning wars that ushered in a massive program of colonization. Since the Roman colonization involved land distribution to colonists, the *centuriatio* was certainly carried out since the earliest colonization and evolved in step with it.

At the conclusion of successful military campaigns, part of the territory belonging to the defeated communities was usually confiscated and annexed to the Roman state domain (*ager publicus populi Romani*). Part of it could be used to settle a colony: military motives were decisive in choosing the site and the type of the colony (Campbell 1996: 82).

In many cases, the colony consisted of a new town and a dependent territory partly centuriated and assigned to the colonists (*colonia*); in other cases, the territory was centuriated and distributed to individual settlers (*assignatio, ager viritim divisus*: viritane settlement or viritane colony) and no town was built; these communities were essentially rural ones, administered directly from Rome and eventually connected to a local administrative or market center (*conciliabulum* or *forum*) (Broadhead 2007: 154).

Prior to 200 BCE, the responsibility for foundations lay with the Roman Senate and in the second century with plebeian tribunes. The plebeian assembly (*concilium plebis*) was determined by law (*lex coloniae*), the location where a new colony was to be settled, the number and legal status (Latin or Roman) of the colonists, funds, and size of allotments, etc. (Broadhead 2007). Founding commissioners were appointed for the various aspects of the foundation. They were of senatorial rank and usually three in number (*tresviri coloniae deducendae [agroque dividundo]*: Campbell 2000: xlix;

triumviri agris iudicandis adsignandis). They enrolled the colonists and directed them while marching and settling in the assigned area; their staff included land surveyors and related assistants.

The colony's territorial boundaries were laid out; the urban and the rural or, in case of viritane colonization, just the rural areas were defined; and part of the territory was centuriated and assigned.

In the Latin colonies (founded up until 180 BCE), allotments were rather large and distributed according to rank. In the Roman colonies, allotments were small in the earlier phase, but then became larger from the early second century BCE.

From the late second century BCE until the age of Augustus, colonization increasingly concerned land obtained through means other than traditional conquest and confiscation: Roman communities were often mulcted of their land in order to satisfy the economically disadvantaged or reward discharged army veterans (Roselaar 2010). From Sulla's dictatorship until the end of the Republic, colonies were founded and land was distributed in Italy by the military dynasts without deferring to the senate (Campbell 1996: 81; Broadhead 2007: 158–162).

Augustus played a crucial role in land distributions to veterans: after the ravages of civil war, he applied procedures which raised confident expectations that the object of government was to preserve property rights and the population would no longer be deprived of their property (Campbell 1996: 98–99). Following his principate, the foundation of military colonies continued until the time of Hadrian, but more soldiers received cash handouts than were settled in military colonies (Campbell 1996: 81).

In the Imperial period, emperors themselves founded colonies. They usually delegated the various tasks connected with the foundation to an agent (Campbell 1995: 541, 1996: 94).

The foundation of a colony was formally started by the founder (a magistrate in the Republican period, the emperor or a member of the imperial family under the Empire) and an *augur*, since the religious and technical aspects were intertwined. The *augur* would take the auspices; in case they were favorable, the founder would duly approve the beginning of the land surveyors' work (Dilke 1971: 89).

The surveyors planned and constructed the centuriation, assigned the plots by drawing lots, and settled possible (and frequent) legal quarrels, as documented by sources including the technical writings in the *CAR*. They were originally called *finitores*, then *metatores*, *mensores*, *agrimensores*, sometimes *decempedatores*, later *gromatici* after the names of their most typical tasks or instruments (Lewis 2001: 3, 21 n 32, 122, 323; Toneatto 2010: 53). The technical aspects of their profession were certainly in progress (Hyginus, *The Establishment of limites*, in Campbell 2000: 135–135, 23) from the earliest times through the Empire and Late Antiquity, but on evidentiary grounds, it is very hard to follow this development in detail. It is clear that the land surveyors had specific professional expertise and training.

In the Imperial period, the nonmilitary surveyors were freedmen, slaves, and possibly free citizens as well (none of these appear to be of senatorial or equestrian rank). The practitioners of surveying remained men of low rank. In the army, surveyors seem usually to be ordinary soldiers ranking among the *immunes* and attached to legions, praetorian *cohors*, and auxiliary units. Military surveyors could be involved in civilian projects both in Italy and in the provinces. In all cases, they executed decisions made by persons of higher status (Campbell 2000: xlvii–lii, l–li and n 150).

When large-scale foundations ended in the second century CE, the surveyors still had important tasks, which included overseeing or enlarging existing settlements, contributing to settle quarrels, and surveying land for the government for taxation, boundary demarcation, or other reasons (Campbell 1996: 98). They maintained an important role in the late empire as well (Campbell 2000: lii: Cassiodorus *Variae* 3.52).

The land surveyors explored the area first; observed the hydrography, slopes, and soil characteristics; and chose the proper orientation of the *centuriatio* in order to provide the territory with adequate drainage. Then they traced a grid of lines (*rigores*) using their instruments, marked them temporarily by means of stones or sticks, and directed the colonists in constructing the infrastructure (roads and ditches/channels) which converted

Centuriation and Roman Land Surveying (Republic Through Empire), Fig. 3 Construction of a centuriated landscape

the *rigores* into a grid of *limites*; eventually other infrastructure was built (e.g., bridges) (Fig. 3).

The standard surveying equipment was unsophisticated: it included the *groma*, measuring tools, plumb-line level, portable sundial, and writing and drawing aids, as documented by written sources (mainly the *CAR*) and archaeological evidence (Dilke 1971: 66–81; Moatti 1993: 31). As for the latter, in 1912 in Pompeii, Della Corte excavated the workshop (*Regio* I.6.3) used by the blacksmith (*faber aerarius*) Verus, who repaired and/or resold objects of various sorts. Among them, those related to the surveying equipment were a *groma* (see below), folding ruler, two bronze compasses, the bronze parts of wooden chests and a key, pincers, a conical ferrule, end pieces of a measuring rod, thin iron tools, an ink bottle and a stylus (evidence of wax tablets for notes and papyrus for writing), pieces of a measuring rod, and a portable sundial, in the form of an ivory box. The gnomon which was used with it was not discovered. On the lid, thirteen converging lines are incised, which showed the daylight hours from first to twelfth without seasonal correction; on two sides, the box has lines with marks indicating measurements (digit, inch??) (Dilke 1971: 70–73).

The principal surveyor's device was the *groma* (*gruma* and the verb *grumare/degrumare* in Republican Latin sources, *groma*/*croma* under the Empire: Lewis 2001: 125). The name derived via Etruscan from Greek *gnoma*, a by-form of *gnomon*. The term is usually applied to a sundial pointer, but could mean any indicator or mark (Dilke 1971: 66, 1974: 569–573; Schiöler 1994; Lewis 2001: 125). The *groma* is most probably the same instrument mentioned as *ferramentum* (iron instrument) by the authors in the *CAR* and was used in military and civilian surveying mainly to establish the orthogonal patterns of land divisions, town streets, and military forts and camps (Lewis 2001: 120–133). The understanding of the *groma* and related operations is

based on archaeological and written sources, but some aspects remain unclear (Lewis 2001: 4, 124). Reconstructions have been proposed on the basis of *CAR* and archaeological evidence.

On the basis of the metallic portions of the device interpreted as a *groma*, found in Pompeii (*Regio* I.6.3), Della Corte (1922) reconstructed the tool (Fig. 4) by adding the wooden parts and the plumb cords, which had perished, in the shape of a vertical wooden staff with a fluted iron shoe. At its top, a horizontal bracket made of wood and iron was fixed by a bronze pivot. At the opposite extremity of the bracket, a wooden cross (*stella*) with four arms (*corniculi*) and iron sheeting was pivoted. Near the end of each arm, a plumb line hung through a hole; a fifth one must have been fixed in the center of the *stella* (Dilke 1971: 69–71, 1974: 569). In Pompeii (*Regio* I.6.3: *Verus*' workshop), four plumb bobs were found, identical in two pairs (Adam 1982; Schiöler 1994: Lewis 2001: 126–129; Figs. 5.1–5.2). Evidence of the *groma* is also provided by low-relief carvings on the tombstones of the surveyor Lucius Aebutius Faustus (from *Eporedia*/Ivrea: *CIL* 5.6786) and of Popidius Nicostratus (from Pompeii, Porta Nocera) dated to the first century CE, both showing parts of a dismantled *groma*.

Centuriation and Roman Land Surveying (Republic Through Empire), Fig. 4 Groma according to Della Corte (1922)

Another fundamental device used in land surveying was the *decempeda* or *pertica*, a 10-foot-long wooden shaft; it was equipped at the end with a bronze ferrule marked in digits or inches for small measurements and flanged so as to abut neatly against its neighbor. Examples were found at Enns (Austria) and Pompeii. The Roman surveyors seem to have used ten-foot shafts in pairs, while there is hardly any evidence that they used cords for measuring long distances (Lewis 2001: 21).

The metal portions of a rigid iron cross, possibly a Roman surveying instrument, were found at Pfünz, on the Roman frontier near Eichstatt (Bavaria, Germany) before 1901 (Dilke 1971: 69, 1974: 569; Lewis 2001: 129).

The surveyors started (Campbell 1996: 82) at a point chosen as the main intersection (*tetrans*) of the orthogonal *limites* which were traced first, the *kardo maximus* and *decumanus maximus*: the intersection could be located at or near the central point of a settlement, on an existing road in a settlement, at a point not far outside an existing or planned new town, and at a distant point from this (Dilke 1971: 88–89). The starting point of any centuriation was called *locus gromae* evidently from the tool (in military camps Campbell 2000; li).

In order to construct the *centuriatio* in line with the chosen orientation, the compass points were preliminarily identified. South was precisely individuated by a sundial or a portable sundial following an established methodology (Hyginus Gromaticus, *Establishment*, 152.4-22; Vitruvius, *Arch*. 1.6.6-7): the surveyor drew a circle on flat soil and put a vertical sundial gnomon in its center. The shadow would at times fall in the circle, at times outside; when the shadow reached the circumference, the point was marked, the same when the shadow left the circle (i.e., before and after noon). A straight line was drawn through the two points and bisected: it identified south. A more complex method, certainly deriving from Alexandrian scholarship, was based on the use of a gnomon, the marking and measuring of three shadows (Dilke 1971: 56–58, 86; Lewis 2001: 22–23, 123).

The surveyor planted vertically the *groma* in the ground, the bracket length away from the chosen center of survey, which was fixed on the soil by a stone or stake and plumbed the *groma* vertical. The horizontal bracket was twirled until its free extremity pivoting the center of the cross (*umbilicus soli*) was vertically above the marker, as checked by plumb lines. The cross was then swung until its arms and cords matched with the chosen alignment (Fig. 5).

Across opposite plumb cords, the surveyor sighted at shafts set by collaborators in order to mark a straight line and across another pair to delineate the orthogonal one. The linear measures chosen for the *centuriae* (mostly 20 × 20 *actus*, 2400 × 2400 Roman feet, 709.68 m, producing an area of 200 *iugera*, 50.4 ha) were progressively marked off in both directions starting from the main intersection (Dilke 1971: 89; Campbell 1996: 84). The operation was repeated until the entire area was surveyed (Lewis 2001: 124, 127). The sighted lines (*rigores*) had no width, were made evident by placing stones or wooden stakes at definite distances, and marked the alignments of the *limites* which, according to the local geomorphology, took the form of roads and/or ditches or channels (Campbell 1996: 84).

The *groma* only enabled straight lines, squares, and rectangles to be surveyed. The Roman surveyors, like the Greek ones, worked with simple Euclidean geometry, notably in the form of similar triangles in the horizontal or roughly horizontal plane (Fig. 6). For arithmetical calculations, they no doubt used the *abacus*, which was well known throughout the ancient world (Lewis 2001: 22).

Whenever the surveyor encountered a steep-sided valley, he carried out the operation known as *cultellatio*. He held a ten-foot rod horizontal with one end resting on the ground at the start of the slope. From the other end, he dropped a plumb line and marked the point where it hit the ground. He moved the rod, still horizontal, so that its uphill end rested on this point; dropped the plumb line again; and so proceeded down one side of the valley and up the other, counting horizontal ten-foot steps but ignoring the vertical

Centuriation and Roman Land Surveying (Republic Through Empire), Fig. 5 Surveyors at work

Centuriation and Roman Land Surveying (Republic Through Empire), Fig. 6 Surveyors at work: the *fluminis varatio*

difference (Frontinus, *Surv.* 18.12-16; Nipsus, *Resighting*, 51–76 seems also to take account of slopes) (Lewis 2001: 6, 124ff). Cross-checks were taken to ensure accuracy of angle measurements (Dilke 1971: 89).

The *decumani* and *kardines* parallel to the *decumanus* and the *kardo maximus* were progressively and respectively traced and labeled DII and KII, then DIII and KIII, and so on. They were called *subruncivi* (weeded, i.e., kept clear) and minimum 8 Roman feet wide, in order to allow two vehicles to pass.

The DM and the KM were, respectively, 40 feet and 20 feet wide in the case of Augustan colonies for veterans, but in some areas, the KM, too, was 40 feet wide (Dilke 1971: 89, 93; Campbell 1996: 84). The *quintarius* was the most important *limes* after the DM and the KM; it closed the fifth *centuria* in both directions, hence its name. It was wider than the *decumani* and *kardines*, had a recommended width of 12 Roman feet, and was identified by stone markers (Campbell 1996: 85).

Within the *centuriae* were usually traced the *limites intercisivi* ("balks which cut inside": Dilke 1971: 93): a *centuria* could be divided by two orthogonal *limites intercisivi* into four equal parts (each of them measuring 50 *iugera* in size), by two parallel equidistant *limites intercisivi* into three equal parts, and by three parallel equidistant *limites intercisivi* into four rectangular areas (Campbell 1996: 85). Access to fields was safeguarded by law (Dilke 1971: 104–105, 124; Campbell 1996: 84).

Each *centuria* was identified by two coordinates related to its location to the right or left of the DM and on the near side of or beyond the KM, conforming to the following nomenclature:

DD (*dextra decumani* or *decumanum*), to the right of DM
SD (*sinistra* decumani or *decumanum*), to the left of DM
UK (*ultra kardinem*, in early times *pars antica*), beyond KM
CK (less correct KK, *citra kardinem*, in early times *pars postica*), near side of KM.

Based on the surveyor standing at the DM and KM intersection and facing the original orientation, the *centuria* in front of him on his right was DDI UKI, the one in front of him on his left was SDI UKI, the one behind him on his right was DDI CKI, and so on. The other *centuriae* were numbered referring to the *limites* progressive number as far as the centuriation went (Fig. 7) (Dilke 1971: 90–93; Campbell 1995: 541–542, 1996: 86–87). The coordinates were inscribed on

Centuriation and Roman Land Surveying (Republic Through Empire), Fig. 7 Each *centuria* was identified by two coordinates

centuriation markers set up at the crossroads and in the surveyor's documents: within this system, the single plots were allocated and precisely recorded (Campbell 2005: 174). Other data could be inscribed, e.g., the specific commission data were added to the coordinates on stones set up by the Gracchan land commissioners (Dilke 1971: 92).

Centuriation stones were either cylindrical or parallelepiped. They have been found in many sites, but the total number appears small if compared with estimates based on the orthodox procedure, according to which markers were to be set up at every crossroad. Even assuming a high casualty rate, this modest number suggests that only a selection was set up in most centuriations. No doubt some crossroads were given wooden markers, as documented by writings in the *CAR* (Dilke 1971: 89, 103–105; Campbell 1995: 541).

While centuriation stones had no religious implication (Dilke 1971: 98), the boundary stones, on the other hand, either single or in groups, were set up with proper ceremonies; removing or changing their position without authorization (*terminus motus*) was deemed a religious and civic offence and punished (Dilke 1971: 98–99): defining and marking the boundaries was a very relevant task of the surveyors (Dilke 1971: 98–108).

A large variety of boundary stones is described and illustrated in the *CAR*. According to the late treatise *De terminibus*, specific boundary stones had to be erected in correspondence of a three- or four-way boundary or of specific components of a

property like wells, water tanks, springs, and streams (Dilke 1971: 103). Natural boundaries were selected too, including groups of trees and isolated trees, which might be thought to be too fallible (Dilke 1971: 103; Campbell 2005: 179–180).

The next steps were parceling and allocating land and sorting the plots (Moatti 1993: 23–26). The specific organization of sortition (*sortitio*) was left to the land surveyors; it is a relevant topic in their writings. In order to allocate the land fairly and prevent disputes, the order of tenure of land plots (*sortes*) was decided by lottery, for which the surveyor used an urn (*urna* or *sitella*) (Dilke 1971: 96–97; Moatti 1993: 27–30; Campbell 1995: 541–542, 545). This practice is documented at least from 133 BCE onward.

The number of *iugera* of each holding was found in one, sometimes two, exceptionally in three, or more *centuriae* (Dilke 1971: 92; Figs. 27, 96, 114). During the lottery procedure, the surveyor recorded the data in preliminary sketches on wax tablets, papyrus, or parchment which formed his ledger. In order to achieve equity, landholdings were routinely assigned by group lottery applying a very complicated system (Dilke 1971: 96, 97, 114; Moatti 1993: 27; Campbell 1995: 542–544, 545). The practice is described in two passages (Hyginus 1, T 14.3-5 and Hyginus 2, T 162.12-164.5). Evidently the aim was being fair to all the settlers and respecting their equal status. The procedure implied a certain amount of literacy and consciousness by the colonists (Campbell 1996: 87–88).

The founder entirely disposed of the land that exceeded the original needs of the colony: he could retain it for himself, give it to friends, endow the colony with it as common pasture or woodland for profit, or restore it or part of it to its previous owners (Campbell 1996: 93).

The next duty of the surveyor(s) was accompanying the colonists in person to their plots in order to prevent any mistake concerning location, size, and boundaries of the allotted properties. When the allocation was concluded, he provided the final official written documents ((a) *libri aeris*, *tabulae*, *commentarii*, *libelli*; *scriptura, instrumentum mensorum*; (b) *libri subsecivorum*, (c) *libri beneficiorum*) and the mapping (*forma*, *forma agrorum*) (Dilke 1971: 97, 112–125; Moatti 1993: 49–62).

One copy of the *forma* and related written documents was usually in bronze. This was estimated as the most reliable material, although wood and parchment were used, too (Campbell 1996: 88–89). The documents were signed by the founder and kept in the colony (Moatti 1993: 73–75; Campbell 1995: 546), while copies of all that evidence, most likely on cloth, parchment, and papyrus, also signed by the founder, were saved in Rome in the imperial records office (Moatti 1993: 49–50, 62, 66–73; Campbell 1996: 88, 90).

The map of the colony (*forma*) was a cartographic, legal, and administrative document normally for public display. Originally, it recorded the *centuriae* and the assigned plots; under Trajan, the size and perimeter of the holdings were added, at least in some cases.

As specified in the *CAR*, on the *forma*, and in the land registers, the surveyor recorded all legal data (*data assignata*, *concessa*, *excepta*) including the various categories of land, e.g., *ager divisus et adsignatus* (divided and allocated), *quaestorius* (given to the *quaestores* for sale in blocks of 50 *iugera*), *arcifinius* or *occupatorius* (land without formal boundary), *ager relictus*, *ager extraclusus* (not encompassed in the land divided by *limites*; Campbell 1996: 79, 2000: 321, 2005: 176–179), and *subseciva*. The last, literally "land cut off by a line" (from verb *subsecare*), was applied to areas located between the *centuriae* and the outer boundary line of centuriated lands or to areas between the exterior boundary and the right-angled lines of other layouts or to areas either included in the *centuriae* but inappropriate for distribution or unallocated because of unavailability of landholders (Moatti 1993: 54; Campbell 2000: 320–321, 2005: 176–177).

Evidently the surveyor was to be well acquainted with land law in force, in order to provide each holding with its precise legal status on the map (Dilke 1971: 114). The word *forma* ("shape") is documented since the mid-second century BCE (Moatti 1993: 88–89): in the sense

we are concerned with, it appears first in the agrarian law of 111 BCE and persists to the end of the empire and beyond (Dilke 1971: 112). Other words for the same document were *aes*, *scarifus*, *typum*, *mappa*, *pertica*, *cancellatio* (Moatti 1993: 32).

We can get a plausible idea of the working maps and the final *formae* produced by the surveyors from the *CAR* and its illustrations, and a few tablets (see below).

On these maps, some geographical features (main rivers, islands, mountains) and the *limites* were drawn; river names and sometimes their width, holdings extension and holders' names, and land status were added (belonging to the Roman people or religious bodies, land given and assigned or excluded from allocation or returned to the previous owners, granted, excepted, restored, and exchanged for own property, *subseciva*, etc.); adjoining territories, public pasture, and woods were entered. Words were written in full but also sometimes abbreviated (Campbell 1996: 89). Such maps had large dimensions and a copy was made for public display in the colony (Campbell 1996: 89).

A bronze fragmentary tablet from SW Spain (area of *Augusta Emerita*) is interpreted as part of a *forma*. It depicts some *centuriae* and their size, the course of the river *Ana* (present Guadiana), and the adjacent territory of the *Lacimurgenses* (Sáez Fernández 1990; Moatti 1993: 33; Campbell 1996: 89). A fragment of a bronze *forma* depicting part of the Verona *centuriatio* was discovered in the Verona *Capitolium* (Cavalieri Manasse 2000) (Fig. 8).

The "Orange tablets," often named "cadasters," are fiscal documents engraved on marble slabs and record a survey made for taxation purposes under the Flavian emperors. Although not properly *formae*, they document Roman surveying procedures (Moatti 1993: 76–77, 91; Campbell 1996: 89, n.60). The tablets (labeled conventionally as A, B, C) were found in fragments in Orange, France (ancient *Arausio*), both in the theater and in a nearby building interpreted as a local *tabularium*. They are engraved with some topographical features (rivers, streams, islands, and roads), the *centuriae* (identified by their coordinates), the number of *iugera* withdrawn from the obligation of *tributum* (*ex tributario*), the number left in possession of the *colonia*, those handed back to the local people *Tricastini* (cadaster B), those belonging to the state (cadaster A), and *subseciva*. Annual rents and names of principal lease holders are specified (Piganiol 1962; Dilke 1974: 573–574).

Centuriatio was applied in some areas (see below) and periods. In other cases, land was parceled applying other systems influenced by local traditions, soil and climate characteristics, and agriculture. Three systems are most frequently identified: allocation by *decumani*, by *laciniae* (narrow strips), by *strigae* and *scamna*. The last were long rectangles of land, the former bounded lengthwise as viewed with the orientation chosen, the latter breadthwise (Dilke 1971: 95). This strip system was pre-Roman but continued under the empire, in some areas alongside centuriation (Dilke 1971: 139–141).

The land surveyors had to be well acquainted with the legislation concerning boundaries and boundary disputes, as they were often charged to resolve or arbitrate boundary quarrels (Dilke 1971: 99, 105–108) arising among private individuals, local authorities, and the state. Fifteen sorts of disputes are distinguished in Frontinus' treatise *de controversiis* (Campbell 2000: 5–49). The surveyors would operate as legal counsellors on arising disputes or as arbitrators or judges in establishing where the boundary line lay and defining the legal position of land within 5 feet of it (Dilke 1971: 99, 105–108) but were not lawyers and did not make the final decision in land disputes (Campbell 2000: xlv–liii, 475–477, 2005: 174).

The grid of centurial *limites* enhanced the local road network and could provide long-distance roads with a relevant framework, when they were constructed contextually or after the *centuriatio*. In fact, in some centuriated territories, the long-distance roads corresponded to *kardines* or *decumani* or to the diagonals of some *centuriae*, while in other cases, they had no connection with the centurial grid and run straight across the territory.

Place-names related with c *enturiatio* mostly derive from technical terms (*pertica, limes, fines,*

Centuriation and Roman Land Surveying (Republic Through Empire), Fig. 8 Bronze fragment of a *forma* from the Verona *Capitolium*

cardo, centuria, possibly *decumanus/decimanus*), from cardinal or ordinal numerals, or from property owner's names (Dilke 1971: 137–138).

The primary written source on *centuriatio* is the *Corpus Agrimensorum Romanorum* (*CAR*): the earliest manuscript probably dates from the sixth century CE. The *CAR* assembles texts written by different authors of broadly differing dates, the main ones dated in the late first-early second to the fifth centuries CE (Campbell 1996: 74–79, 2000: XX).

The writings manifest a relevant diversity of interests and approaches; since they were edited and excerpted in transmission, we cannot identify the criteria applied in making the compilation.

On the whole, they were presumably produced with didactic aims for practicing and/or apprentice surveyors. Specific examples from Italy and the provinces are provided, often derived from vast personal experience; relevant test cases and hypothetical problems are tackled; the complexity of the surveyor's job is evident (Campbell 1996: 79–80).

Moreover, some manuscripts of the *CAR* preserve illustrations aimed at illustrating issues in the technical texts and/or teaching assumptions. They are of several kinds and include maps of

divided land, scheme, and layout of *limites*, boundary marking and boundary stones, astronomy, and geometry (Dilke 1971: 115–125; Campbell 1996: 99, 2000: xxiii–xxvi). We cannot date such illustrations with certitude, but their significance to the subject is indubitable.

After the early Middle Ages (Toneatto 1994–1995; Del Lungo 2004), the origins and characteristics of *centuriatio* were gradually forgotten, although in many areas of the Roman world, more or less evident traces of such land division remained throughout centuries.

Thanks to the *CAR* and other ancient texts, *centuriatio* was rediscovered after centuries. By the Renaissance, the scholars of Roman metrology had calculated the equivalent of a normal *centuria* (200 *iugera*) based on written sources, while evidence of *centuriatio* in the landscape was rediscovered in 1833, when Captain C. T. Falbe, Danish consul in Tunis, surveyed the Carthage territory using a pocket sextant, identified square areas 708 × 708 m average, and interpreted them as *centuriae* based on Appian (*Bella civilia* 1.3.24). He reported the results of his investigations to the Académie des Inscriptions et Belles-Lettres (Falbe 1833).

In the 1840s–1860s, E. N. Legnazzi, P. Kandler, E. Lombardini, and others made alike observations in the territories of North East Italy and Pola (Settis 1983: 170–173).

In the meantime, in 1848–1852, most of the technical texts in the *Corpus Agrimensorum Romanorum* were edited in Berlin by F. Blume, K. Lachmann, and A. Rudorff. The publication stimulated surveys and archaeological research.

In the 1890s, Beloch studied the Campanian centuriation and Schulten provided systematic comparisons between land evidence and Latin sources; in 1912, he also proposed the reconstruction of the *groma* on the basis of the *CAR*. In 1911, Barthel published a study of North African centuriations and observed the extensive remains in many areas of Tunisia and the limited evidence in other districts of North Africa.

C. Thulin published the *Corpus Agrimensorum Romanorum* (Leipzig 1913; reprinted 1971); in 1912, Della Corte found elements of the Pompeii *groma* and proposed a reconstruction based on the Pompeii fragments in 1922. Further studies in Italy provided evidence of *limitationes* in the Po valley and other areas (Fraccaro 1957, esp. years 1937–1956; Castagnoli 1943–1964). Later on, the study of *centuriatio* has identified many centuriated landscapes (Dilke 1971: 141–158) in Italy, southern France, Spain and Portugal, the Netherlands (?), Belgium, Switzerland, Dalmatia, Greece, and North Africa (mainly Tunisia). The literature on this subject is enormous (Dilke 1974: 585–592; *Agri Centuriati*; etc.).

Traces of Roman field systems in Britain, Germany, and adjacent areas, where land patterns do not conform to the orthodox *centuriatio* scheme, are receiving increasing attention (Dilke 1971: 158, 188, 191, 1974: 565; Peterson 2009; and http://www.uea.ac.uk/~jwmp/). Recently, scholars' interest returned to the *CAR*: Campbell (2000) has selected a certain number of writings and omitted a few others, while individual texts (notably Frontinus, Siculus Flaccus, and Hyginus) were edited by several authors in the frame of an European COST G2 project under the direction of M. Clavel-Lévêque (1993, 1996).

Future Directions

Centuriation is a key subject in Roman history, archaeology and law, in landscape and settlement archaeology, history of science and technology, and Roman social and economic history. It is very complex topic closely linked with the study of unorthodox field systems and with earlier and later orthogonal land divisions (Dilke 1971: 201–211).

The current debate is and should be increasingly focused on investigating centuriations applying a long-term diachronic perspective and an interdisciplinary approach: the systematic integration of palaeogeographic and environmental studies, written and archaeological sources *in* the historical background, is fundamental, as well as the application of computer-assisted analysis and, in particular, of GIS (geographic information systems).

Updated research methodology integrates landscape-based methodologies and approaches (Orengo and Palet Martínez 2009), remote sensing, geophysical and archaeological surveys, and

historical research in a long-term perspective. Some research directions that remain to be developed are:

Define efficient strategies finalized to identifying the *limites* and testing the *centuriatio* proposal (Orengo and Palet Martínez 2009: 179–180).
Establish closer links between geomorphology, paleogeography, and centuriations, in order to link hydrography and subsoil architecture with local landscape evolution and centuriations (planning, continuity, or discontinuity).
Provide systematic paleobotanical analysis in order to assess the *centuriatio* impact on local vegetation (agriculture, deforestation).
Origins and development of *centuriatio* (chronology, metrology, technical aspects).
Methods of dating centurial grids and other field systems.
Define the paleogeographic or historical explanations of entirely or partially overlapping centuriations.
The dynamics of continuity or change of centurial systems or part of them and the related causes.
The pre-Roman field systems and their possible influence on the Roman ones both in Italy and in the provinces.
The "unorthodox" field systems and their complexity.
The rural settlements (villages, villas, farmsteads, kilns, tombs) in the centuriations, in a long-term diachronic perspective.
The impact of centuriations on the local rural economy and social history.
Conservation and management strategies of centuriated areas as cultural landscapes.
Development of digital technologies applied to the study of *centuriatio* and other field systems of the Roman world.
Visualize the results of research properly.
The textual, philological, historical, and archaeological studies should proceed applying an interdisciplinary approach.

Ceramic Ecology

Charles C. Kolb
Division of Preservation and Access, National Endowment for the Humanities, Washington, DC, USA

Introduction

The concept of ceramic ecology forms a basis of the investigations reported by archaeologists, ethnographers, and others in which emphasis is placed upon the technological and socioeconomic aspects of ceramic materials regardless of chronology or geography. The initial framework was proposed by Frederick R. Matson (1912–2007) in "Ceramic ecology: an approach to the study of the early cultures in the Near East" in his edited volume, *Ceramics and Man* (Matson 1965b). Matson – a ceramic engineer, archeometrician, ceramic ethnoarchaeologist, and ethnographer – stated as a basic premise that "unless ceramic studies lead to a better understanding of the cultural context in which ceramic materials were made and used, they form a sterile record of limited worth" (Matson 1965a: 202). His students and colleagues have employed, modified, and expanded the concept.

This article focuses on the concept, its historical background, evolution into mid-range theory, methodological adaptations, critiques, misconceptions, and international perspectives. The formation of the Ceramic Studies Interest Group and annual Ceramic Ecology Symposia is also documented.

Definition

Ceramic ecology as a methodological and mid-range theoretical approach has as its paramount goal a better understanding of the peoples who made and used pottery and seeks to redefine our comprehension about the significance of these materials in human societies. The concept is contextual, multi- and interdisciplinary, and analytical. On the one hand, it seeks to evaluate data derived from the application of physiochemical methods and other techniques borrowed from the physical sciences within ecological and sociocultural frames of reference. Its holistic considerations seek to relate environmental parameters, raw materials, technological choices and abilities, and sociocultural variables to procurement of resources (clay, temper, and fuels), the manufacture, decoration, distribution, and use of pottery vessels and other ceramic artifacts. Hence, it spans the cycle of "birth" (fabrication) through "death" (ultimate use or discard). On the other hand, interpretation of these data and explanations of the ceramic materials and products utilizes methods and paradigms derived from the social sciences, humanities, and the arts. Ceramic ecology approaches fundamental anthropological questions, such as the socioeconomic context of production, social systems of learning, communities of practice, the formation of identity, and the effects of economic development. It also demonstrates the value of the cross fertilization which results when investigators ranging from art historians and professional potters to ethnoarchaeologists and archaeometricians come together in a forum devoted to a topical consideration: ceramics. Ceramic ecology provides an open and supportive venue for the presentation of research and insight on *all aspects* of ceramic production, consumption, trade and their economic, political, social, aesthetic, cosmological, and phenomenological implications. It concerns the relationships of ceramics, society, and the environment; it is not solely about the ceramics themselves (Arnold 2011: 63). Hence, it is analogous to the *châine opératoire* in lithic analysis suggested in 1964 by Leroi-Gourhan but goes well beyond production, and ceramic ecology also combines the theoretical perspectives of systems theory and cybernetics with cultural ecology (Kolb 2011; Roux 2017; Duistermaat 2017: 115–116). The paramount issue is for the investigator to be knowledgeable about the variables and their interactions and account for these in the research design and subsequent enquiry whether it is archaeological

ethnoarchaeological, ethnographic, social anthropological, and/or archaeometric materials science.

Historical Background

Ceramics are one of the tangible products of human culture and are relatively widespread among cultures of the world. Pottery making is one of the oldest crafts known to humankind and was innovated independently in different parts of the world at different times in extremely diverse social, economic, and ecological settings. Ceramics constitute an important source of information for archaeologists, art historians, and scholars of social and cultural phenomena (historians, social scientists, and humanities scholars), among others, because, being created by human beings, these artifacts encapsulate a wide variety of human behaviors and have become an essential tool for archaeologists who study past human lifeways. Ceramic products, therefore, may be studied from a variety of humanistic and social and natural scientific perspectives: artistic, art historical, aesthetic, archaeological, historical, typological, classificatory, stylistic, mineralogical, physicochemical, mechanical, and thermal, to name only a few. Scholars have an interest in the history of pottery manufacture, especially regarding the roles of the innovation and diffusion of technologies. Archaeologists pay particular attention to the types and sources of the raw materials used in pottery fabrication, including clays, inclusions, impurities, liquids, and fuels for firing. Materials science specialists and archaeologists concerned with physicochemical analyses are interested in documenting and understanding the properties of clays (plasticity, drying, shrinking, and physical and chemical changes during processing and firing), the manufacturing techniques, processes, and tools (forming, finishing, and decorating, including styles and stylistic analyses), and the drying and firing of the products. Socioeconomic and behavioral parameters of production (location, organization, scale, and mode) and mechanisms of distribution or exchange are of interest to investigators. Vessel function and classification systems (folk or derived), uses, reuses, and ultimate disposition or discard are growing areas of research (Kolb 1989c, 2001, 2011, 2017a).

Scholars have developed a multitude of procedures for quantifying and classifying archaeological and ethnographic ceramic materials, many of which focus on establishing the loci of manufacture (provenance) and production processes and ascertaining the time of manufacture, i.e., absolute or relative chronology. The methodologies employed include ethnoarchaeology ("Further Reading": Kramer 1985; Longacre 1992), behavioral archaeology and life histories, attribute analysis, ethnotaxonomies, devised and formal classifications, and a variety of physicochemical techniques ranging from basic macroscopic assessments, petrographic thin-section studies, and micromorphology to geoarchaeology and NAA (Vandiver 2000; Maschner and Chippindale 2005; Rice 2015; Kolb 2017b).

Investigators have also postulated a number of theoretical approaches to the study and analysis of material culture including ceramics, among these are evolutionary theory, ecological anthropology, processualism (stimulated by ecology, physics, and cultural anthropology), postprocessualism, gender archaeology, ethnoarchaeology, systems theory, formation theory, complexity theory, engagement theory, agency theory, materiality, and technological style, among others. The coalescence of ecological anthropology and the "New Archaeology," championed by Louis Binford, contended that ethnoarchaeology and other middle-range approaches, both theory and research, were fundamental to making an intellectual leap (Hodder 1985; Schiffer 1976; Bentley et al. 2009).

Cultural Ecology and Ceramic Ecology

In *Theory of Culture Change*, Julian Steward (1955) sought to demonstrate that social systems arise out of patterns of resource exploitation which, in turn, are conditioned by the technological adaptation of a people to their natural environment. He delineated "multilinear evolutionism," which

"is like unilinear evolution in dealing with developmental sequences, but is distinctive in searching for parallels of limited occurrence instead of universals" (1955: 14–15). Although there may be cross-cultural similarities of social change, the constraints of different physical and historical settings produce different social manifestations in each case, resulting in to develop a methodology for determining regularities of form, function, and process which occur cross-culturally. Some scholars argue that "pluralistic" evolution is a more appropriate term for Steward's scheme.

Steward (1955: 30–42) also defined cultural ecology as "a heuristic device for understanding the effect of environment upon culture" and perceives culture as evolutionary – that cultural adaptations have come as the result of a changing environment. It combines ideas and approaches of both the natural and social sciences and seeks to explain the social sciences by the means of the natural sciences. The concept is interdisciplinary where anthropology and ecology overlap in the study of human adaptations to physical and social environments or how people interact with each other within their environmental context. Human adaptation refers to both biological and cultural processes that enable a population to survive and reproduce within a given or changing environment.

By 1959, half of the anthropology faculty (three of six) at The Pennsylvania State University, who had received their doctorates at Harvard University after World War Two, had embraced Steward's concepts of human adaptation, especially cultural ecology. Biological anthropologist Paul T. Baker and Mesoamerican archaeologist William T. Sanders became exemplars of these concepts and would influence dozens of graduate students over the next three four decades and other faculty members (Baker 1962; Baker and Sanders 1972; Sanders et al. 1979).

One of the senior faculty members in the department who was intrigued with cultural ecology was Professor of Ceramics and Professor of Archaeology as well as Assistant Dean for Research in The College of the Liberal Arts – Frederick R. Matson, who obtained his doctorate in Ceramic Archaeology at the University of Michigan in 1939. In 1961 Matson organized and chaired a symposium, "Ceramics and Man," sponsored by the Wenner-Gren Foundation held at Burg Wartenstein castle in Austria, September 2–12, 1961. The symposiasts included seventeen archaeologists and ethnologists who had international reputations as experts on pottery to assess ceramic contributions to archaeological and ethnological research. Matson's contribution was "Ceramic ecology: an approach to the study of the early cultures in the Near East" in the published symposium contributions which he edited: *Ceramics and Man* (Matson 1965b). He observed that ceramic studies needed to become holistic, observing that ceramic ecology was but one facet of cultural ecology "that which attempt to relate the materials and technologies that the local potter has available" in his/her culture of the products being fashioned (Matson 1965a: 216). Matson's secretary, Cathy Rusnak, typed the book's manuscript on an IBM Selectric typewriter and the contents were fact checked by his teaching and research graduate student assistant, Charles C. Kolb. Matson would go on to fine tune the method ("Further Reading": Matson 1995). For additional details see Kolb (1988a).

Later History and Modifications

Many of Sanders' Mesoamerican archaeology students and colleagues were also influenced by Matson's perceptions about ceramic ecology, and this was evident especially in the Teotihuacan Valley Project in central Mexico and subsequently in the Copan Project in Honduras. Among them were Charles Kolb, Louana Lackey (1926–2005), Prudence and Don Rice, Robert Santley (1948–2006), and James Sheehy. Other scholars were also drawn to the method and theory, especially Dean Arnold, Marilyn Beaudry Corbett, Elizabeth Chilton, Michael Deal, E. Christian Wells, Eduardo Williams, and Ezra Zubrow. Their colleagues and students, notably Philip Arnold III, Marilyn Beaudry Corbett, George Bey III, Anabel Ford, Michael Galaty, Amy Hirshman, Sandra López Varela, Kostalena Michelaki, Christopher Pool, and Marcia Selsor, also employed aspects of ceramic ecology.

Santley's students George Bey and Christopher Pool (1992; Pool and Bey 2007) and Philip Arnold (2003) employed the concept in their Mexican Gulf Coast archaeological research and teaching.

Dean Arnold's classic monograph, *Ceramic theory and cultural process* (1985), employed principles of ceramic ecology, as did his research Peru (2003) and four decades of intensive study in the pottery-making village of Ticul, Yucatan (2008, 2015, 2017). His reevaluation of the 1985 volume in *Ethnoarchaeology* (2011) reflects his perceptions conditioned by 25 years of ceramic ecological studies. (The texts of more than 70 of Arnold's publications are online at https://fieldmuseum.academia.edu/DeanArnold.) Ethnoarchaeologist and professional potter Louana Lackey's work in Acatlán, Puebla (1991) and archaeologist James Sheehy's detailed assessment of pottery-making at the archaeological site of Tlajinga 33 in the Teotihuacan Valley (1992) were likewise grounded in ceramic ecology. Matson's best-known student, Prudence Rice, published widely on ceramics and Maya archaeology; four of her 11 books focus on pottery, including *Pottery analysis: a sourcebook* published in 1987, now in a second edition (2015). Charles Kolb employed ceramic ecology as the primary methodological approach in his research on archaeological ceramics from Classic period Teotihuacan, Mexico: Thin Orange Wares (1986), Granular Wares (1988b), and Copoid Wares (1988c). He also used the method and theory in an assessment of Kushano-Sasanian ceramics from Central Asia (1989a) and white clay tobacco pipe studies in the Lake Erie Basin ("Clay Tobacco Pipes," *Encyclopedia of Global Archaeology*, 2nd ed., in press).

Arnold (1975: 183) noted that Kolb (1976) had redefined ceramic ecology in his review of the literature on South American ceramic technology from an ecological perspective and perceived a significant relationship in mending systems theory, cybernetics, and ceramic ecology (Arnold 1985: 9–10). Rice (2015: 210) remarked that ceramic ecology has been criticized along the same lines as cultural ecology was decades earlier – as narrow determinism or possibilism. However, ceramic ecology does not posit that "the physical environment controls pottery-making but establishes circumstances within which potters' decisions may be supported or constrained as they practice their technologies." Albero (2014: 142–145) erred in stating that ceramic ecology is "deterministic" and incorrectly stated that it "excludes explanations which involve the significant cultural variability documented in the way raw materials are exploited." He opined that "relevant social, cultural, symbolic, ideological or political parameters" are neglected. His statements rested primarily on the work of ethnographers grounded in social anthropology (particularly Africa by Gosselain and Livingstone Smith), and he does not consider any of Arnold's book-length ethnographic treatments on Ticul, Yucatan potters (2008, 2015, and 2017) or his relevant articles or book chapters. The literature employing ceramic ecology in archaeological, ethnohistoric, and ethnographic studies in Mesoamerica, North America, and Asia (Afghanistan, India, and China) has not been adequately examined by Albero, for example, see "Further Reading": Góes Neves (2008), Manibabu Singh (2001), Osband (2014), and Wallis et al. (2015).

Galaty (2017: 147), in reviewing the Type-Variety System of pottery classification, recommended that archaeologists working with pottery from North America and the Mediterranean region pottery would benefit by adopting ceramic ecology as an analytical procedure. Williams (1992, 2017: 18–19) remarked that ceramic ecology has become established as an analytical approach to ceramic materials with contextual, multi-, and interdisciplinary perspectives through which researchers seek to place physical and scientific data in an ecological and sociocultural framework by relating the technological properties of raw materials to the manufacture, distribution, and use of ceramic products within social contexts. Ceramic ecology he commented (2017: 19) perceives cultural systems holistically, observing that Kolb (1989b: 315, 320, 324–327) developed a model that allows us to obtain a clear grasp of "holistic ceramic ecology." This model is a combination of ceramic ecology (the ecological components of the physical environment, the biological environment, human biology, and culture) and General Systems Theory (Pool and Bey 2007: 17–20). Ceramic production and distribution

focus on a ceramic complex that consists of a cultural system and an environmental system, each one with subsystems necessary for the operation of the complex. The cultural system includes the following subsystems: economic, social, religious, psychological, and the ceramic production subsystem itself. The environmental system consists of physical, biological, and environmental-cultural subsystems. The pottery production system links the economic subsystem (efficiency and skills, resources/raw materials, manufacturing stages, distribution and exchange, and subsistence activities) and the social subsystem (including social organization as well as sociocultural and sociocultural components). These systems and their respective subsystems are mutually linked by feedback mechanisms. The key component of the ceramic complex is the ceramic production subsystem, which contains the main variables that affect the production of a clay object: from raw material procurement to the use and discard of the vessel at the end of its functional life. However, Kolb's model fell short in detailing the nature of interrelationships among the variables.

The factors that distinguish a specifically ceramic ecological approach are its explicit integration of the natural and social environments as components of the ecological system in which humans participate and its concern with subsystem interactions. These allow ceramic ecology to "[provide] a broader perspective on the role of pottery in a culture from archaeological, technological, and ethnographic viewpoints" (Rice 1987: 317). Political economy offers insights into the relation of craft production and exchange to the social realm, dynamics of sociopolitical systems, and emphasizes the social, political, and environmental contexts of the economy dovetailing with the interests of cultural (and ceramic) ecology (Kosakowsky et al. 2013; Pool 1992; Pool and Bey 2007: 20).

International Perspectives

"Ceramic Ecology Revisited: A Pot for All Reasons" was the title of a volunteered symposium held during the annual meeting of the American Anthropological Association (AAA) in Philadelphia, Pennsylvania, in December 1986. The session had eight presentations and was co-organized by Charles Kolb and Louana Lackey (1926–2005) and chaired by Kolb. The organizers had attended previous AAA meetings and observed that papers on ceramics were scattered throughout the meeting and that there was no central forum for presentations on the subject. Hence, the Ceramic Ecology Symposium was organized and Frederick R. Matson, who served on Kolb and Lackey's doctoral committees as well as the committees of several other participants, was the honored guest, and volunteered to be the discussant. The presenters included Canadian Michael Deal, professional potters, physical scientists, and archaeologists as well as ethnoarchaeologists. Fewer than half of the symposiasts were Mesoamericanists, while others presented their research on ceramics from Maine-New Brunswick, the Central Andes, Spain, Morocco, Greece, and Japan. The organizers, symposiasts, and Matson went to dinner together afterwards and continued to discuss the presentations in terms of methods, results, and theories. From the stimulating conversations, it became quite clear that researchers who were working in different areas of the world were learning from one another. Matson suggested that the group be expanded to include anyone who worked with ceramic materials, and the "Ceramic Studies Interest Group" was created and it was determined that a follow-up meeting be held at the subsequent AAA meeting. In addition, the opportunity to publish the presentations as a paperback book came from Muriel Kirkpatrick at Temple University. Hence, *A pot for all reasons: Ceramic Ecology revisited* (Kolb and Lackey eds. 1988) was published and the volume was dedicated to Matson. The monograph contained a "Preface" that included additional details about the symposium and several chapters authored by Kolb, among them "Frederick R. Matson: A Professional and Personal View" (1988a) and a bibliography of Matson's publications.

A tradition had been established and a Ceramic Ecology (CE) Symposium was volunteered for inclusion in subsequent AAA annual programs. The Interest Group also expanded from its original Mesoamerican base and increased its

international membership. As of the Fall of 2017, there have been 31 symposia and five volumes of published papers ("Further Reading": Kolb (ed.) 1988 & 1989; and López Varela (ed.) 2014 & 2017). The Interest Group currently has more than 400 members; 266 authors and co-authors have presented 354 papers. North Americans (USA) dominate the number of presenters, but 39 other colleagues from 15 nations have given presentations; Mexicans and Canadians are well represented, but symposiasts have also come from Australia, Belgium, PR China, Ecuador, Germany, Greece, India, Israel, Japan, Poland, Spain, the United Kingdom, and Uganda. Participants have included three sets of husband and wife teams, a mother and son, and a family (Arlen, Diane, and 17-year-old son Aubrey Chase). Known ages of presenters spans 17–84 years. Eight symposiasts or discussants have received the Society for American Archaeology's "Award for Excellence in Ceramic Studies," including William A. Longacre, Frederick R. Matson, Prudence M. Rice, Dean E. Arnold, Ronald L. Bishop, Robert Rands, Warren R. DeBoer, Carol Kramer, and Hector Neff.

The symposia were co-organized by Kolb and Lackey (until her death in 2005) through the 25th CE symposium in 2011 at which time Sandra López Varela (originally at the Universidad Autónoma del Estado de Morelos and currently teaching at Universidad Nacional Autónoma de México) and Kostalena Michelaki (originally from McMaster University, Hamilton, Ontario, and now at Arizona State University) assumed the roles of co-organizers and alternate annually as chairperson. The symposia are volunteered sessions at the American Anthropological Association annual meetings, in the main, because of the holistic, inclusive orientation of the group and the numbers of nonarchaeologists, professional potters, art historians, and others who attend. The vast majority of ethnoarchaeologists and archaeometricians belong the both the AAA and SAA. The sessions adhere to the goal of including undergraduate or graduate students among the annual presenters. The meetings also offer the opportunity for young investigators to give presentations to a friendly peer group and to get feedback from ceramic scholars in a mentoring relationship. It has also been a mechanism whereby authors present versions of papers or book chapters for review prior to publication – Dean Arnold is, perhaps, the best example with a dozen presentations (Arnold 2003, 2008, 2015, 2017).

Future Directions

As Matson wrote 50 years ago "unless ceramic studies lead to a better understanding of the cultural context in which ceramic materials were made and used, they form a sterile record of limited worth" (Matson 1965a: 202). Materials scientist Vandiver (2000: 373) echoed that statement "to learn about our history and the human condition is not just to analyze and preserve the objects but also to investigate and understand the knowledge and skills used to produce and use them." Ceramic ecology will continue to make strides in understanding the who, what, when, where, why, and how of pottery.

State of Knowledge and Current Debates

Introduction

The use of clay for producing figurines is known from late Upper Paleolithic sites in Europe and northern Africa (from 26,000 years ago), while the first production of pottery vessels is well known in Eastern Asia (Eastern Siberia, China, and northern Japan) from the end of the Pleistocene (Jordan and Zvelebil 2009). Hunter-gatherer groups of northern Africa, the Sahara, sub-Saharan Africa, and the Sudan, according to the present evidence, started producing pottery at the beginning of the Holocene at about 10,000 years ago (Huysecom et al. 2009). Since its introduction, pottery has been one of the major cultural markers of the successive civilizations who settled the Nile River banks of the Sudan (Fig. 1). Following its evolution is thus a way to approach the complex history of this area where various populations moved, exchanged goods and ideas, and influenced each other's development. But as part of a complex system, pottery is only one of the features that define a culture and some other material studies might soon allow to precise and correct the words written below.

The Mesolithic Context of the Sudan

Early Holocene pottery-using hunter-gatherer-fishers in Sudan were first identified by Antony John Arkell in 1944–1945 with the excavation of the Khartoum Hospital site (Arkell 1949). Since then, a number of sites of this period have been excavated in central Sudan, the Wadi Howar and the Bayuda (see Salvatori 2012 Appendix 1 and bibliography therein). Evidence of pottery-using hunter-gatherers was brought to light in the Lower Nubian western desert (Nabta Playa) by the Combined Prehistoric Expedition (Wendorf et al. 2001; Nelson et al. 2002), and this work provided the first comprehensive archaeological sequence of the area for the early and middle Holocene cultural phases (Fig. 2). More recently, the Swiss archaeological mission at Kerma has provided a cultural sequence for Upper Nubia that can be compared to the Nabta-Kiseiba one. In southern central Sudan, the Italian Archaeological Mission has established a Mesolithic local sequence from the late eighth to mid-sixth millennium BC (Salvatori 2012).

Mesolithic Pottery in Lower and Upper Nubia (Fig. 3A)

The Mesolithic pottery and cultural sequence of western Egyptian desert and Upper Nubia are divided in four phases:

Mesolithic I: The few potsherds dating to this very early period (8300–7800 BC) are decorated with a Rocker stamp dots packed motif (Fig. 3A.a), possibly done by mean of a clay "roulette," and alternating pivoting stamp (APS) motifs. All the Mesolithic pottery both in Upper Nubia and central Sudan is made using the coil technique. The vessels are sand

tempered with rare vegetal elements. This early pottery is present in the El Adam phase in Nabta Playa as well as in the Kerma area at Busharia Sites 44 and 45, Wadi el Arab Site 41, and Site 84 south of El Barga. In the Kerma area, potsherds are decorated with Rocker stamp dotted zigzag packed (Fig. 3A.h) or spaced and different patterns of APS. Possibly contemporary is the pottery from Wadi el Akhdar 83/33 (8310–8248 BC).

Mesolithic II: Stem and leaf motifs (Fig. 3A.b) together with early APS seem to be the most typical decoration on the pottery of this period in the Kerma area (Busharia Site 44, El Barga I and Wadi el Arab II dating ca. 7800–7200 BC). It is also well represented in the El Ghorab sub-phase of Nabta Playa as well as in the first phase of the so-called Khartoum Variant horizon, with sites distributed along the Nile from Wadi Halfa to Sai Island and to the Fourth Cataract area. Analogous motifs are present in Upper Nubia at Sai, to the Fourth Cataract dam basin (Mograt Island, Umm Klait Site 3-Q-73) and the Nubian Eastern Desert.

Mesolithic III: This phase (ca. 7200–6300 BC) is characterized by Rocker stamp and APS techniques using combs and cord-wrapped and double-pronged tools to obtain decoration motifs such as zoned dotted wavy line (DWL) patterns (Fig. 3A.d–e), Rocker stamp dotted spaced zigzag (Fig. 3A.f), wolf-tooth or herringbone patterns (Fig. 3A.c), and possibly slightly different stem and leaf motifs and other types of impression. Many of these decorative motifs are known at Wadi el Arab III–IV as well as in the El Nabta third sub-phase of Nabta Playa. Similar motifs are documented in the Nubia Eastern Desert, at Sai and in the Fourth Cataract (Wadi Abu Dom, Mograt Island, Bonny Island, and Shemkhiya site UCSB 03–22).

Mesolithic IV: This phase (ca. 6300–6000 BC) is known at Wadi el Arab V and is characterized by Rocker stamp dots packed sometimes associated with DWL and Scraping on the external surface. It possibly corresponds to a late Al Jerar sub-phase of the Early Neolithic of Nabta Playa. Rocker stamp impressions are widespread all over the area from Nabta Playa to the Fourth Cataract.

Immediately to the south of a line from Debba to Korti (Multaga area), a survey conducted by the Southern Methodist University in the winter of 1966–1967 located Mesolithic sites with pottery apparently correlated with the Early Khartoum horizon (or Khartoum Mesolithic) but mostly with vegetal temper. This was named the Karmakol group. In 2002–2003 a new survey of the area was conducted by the Section française de la direction des antiquités du Soudan (SFDAS), locating seven Mesolithic sites and collecting the same type of pottery which could be directly dated to ca. 6400–6200 BC (Gatto 2006). Two different groups are present: vegetal-tempered and mineral-tempered pottery. The vegetal-tempered pottery assemblage is characterized by globular jars and bowl of both open and restricted forms. Decoration is mainly Rocker stamp dotted zigzag impressions and DWL on both temper type groups, while Incised Wavy Line (IWL) seems to be confined to the vegetal-tempered group. Whether the two productions are contemporaneous is not clear as the abovementioned dates are from the vegetal-tempered sherds only. Karmakol-group pottery is also known in the Letti Basin, north of Hambukol. Sherds pertaining to this distinctive type of pottery have been found sporadically in the Fourth Cataract area. In spite of general similarities with the Early Khartoum Horizon and with Holocene Nubian pottery, the Karmakol-group pottery production seems to denote a discrete human group with its own traditions and identity both in pottery and in lithic production.

Central Sudan Mesolithic (Fig. 3B)

After the publication of the Khartoum Hospital excavation, in which, unfortunately, no stratigraphy was recognized (Arkell 1949: 4), further Mesolithic sites have been investigated in the area of the Atbara junction with the Nile (Aneibis, Abu Darbein, El Damer), in the Butana (Shaqadud), and in central Sudan, along the eastern bank of the Nile to the north of Khartoum (Saggai), as well as along the western bank of the Nile (Umm Marrahi and Sarourab) and next to the Sixth Cataract (Sabaloka). A Spanish expedition surveying an area southwest of Khartoum, on the east of the Blue Nile, located at least 26 Mesolithic sites and made test excavations at the most promising of them (El Mahalab and Sheikh Mustafa).

In the last 17 years, an Italian Mission intensively investigated the western bank of the White Nile from Khartoum to the Jebel Aulia Dam, conducting excavations at a number of Mesolithic

sites mainly in the Al Khiday area (Salvatori 2012 and Appendix 1 and bibliography therein).

Further south, 110 km from Khartoum, a Mesolithic site (Shabona) was investigated by J. Desmond Clark in 1973. Mesolithic pottery related to the Khartoum Mesolithic horizon was also found at Jebel Moya, in the Gezira, 245 km south of Khartoum. To the west of the Nile, an important Mesolithic site (Rahib 80/87) was excavated, in the area of the Middle Wadi Howar.

In spite of the relatively large number of Mesolithic sites excavated or simply tested in central Sudan, a reliable archaeological sequence for the period is far from being established. Almost all of the excavated and tested sites were badly destroyed by postdepositional disturbances (see Salvatori 2012: Appendix 1), and the many radiometric determinations from charcoal, shell, and other materials are never associated with discrete pottery assemblages. This is especially regrettable because some of the C14 dates from sites such as Sarourab 2 and Umm Marrahi cover most of the ninth millennium BC.

A Mesolithic sequence for southern central Sudan, based on stratigraphic excavations and radiometric determinations, comes from sites of the Al Khiday area. It covers the period from the late eighth to mid-sixth millennium BC and allows us to recognize changes in the decorative motifs.

The oldest period (Early Mesolithic: >7000–6750 BC) is documented by basal layers at the sites16-D-5 and 16-D-3, and it is characterized by IWL decoration (Fig. 3B.d–e) on pottery tempered with feldspar grains with angular edges; a small quantity of IWL with flat ridges (Fig. 3B.f) is sand tempered; pottery with incised "Lunula" motifs (Fig. 3B.a) is tempered with sand often associated with calcareous and ochre grains and vegetal temper, as well as deep dots or drops and Rocker stamp deep fanlike motifs (Fig. 3B.b–c). Rare DWL (Fig. 3B.h–i), Rocker stamp plain and dotted zigzag spaced, and Scraped sherds are also present, always mainly sand tempered with the addition of other elements. It is interesting to note that Lunula-type decoration is known only at the Khartoum Hospital site (Arkell 1949: Pl. 77: 2). Most of the potsherds and especially those decorated with the Lunula and the Rocker stamp deep fan-like motifs are covered with a red-ochre slip.

Later (Middle Mesolithic A: 6750–6500 BC) an important change occurred with the abandonment of light huts and possibly residential mobility in favor of mud-walled houses and reduced residential mobility. Lunula-type decoration, as well as a pottery type decorated with punctuations below the rim (Fig. 3B.g) (Salvatori 2012: Fig. 22–23), and IWL with flat ridges disappear, while unpatterned deep drop motifs continue to be applied, but to a lesser extent. Rocker stamp fan-like decoration increases in occurrence, while the execution is less deep than previously (Fig. 3B.l–m). No substantial difference can be noticed in the presence of other decoration types such as DWL, Rocker stamp plain and dotted zigzag spaced, and Scraped sherds.

A further phase (Middle Mesolithic B: 6500–6200 BC), while present at the 16-D-5 site, is better known from the close functional areas named 16-D-4 and 16-D-4B, where more than 150 large and deep pits of varied use, mostly filled with cultural remains (*Pila* sp. shells, fish and mammal bones, lithic and bone tools, and pottery sherds), have been excavated.

This phase shows a consistent decrease in the presence of IWL and a parallel increase in Rocker stamp dotted zigzag packed decoration (Fig. 3B.o–p) on a ware tempered, like the IWL, with angular feldspar grains. The more frequent decoration type is now the Rocker stamp fan-like and Rocker stamp drops with shallower impressions (Fig. 3B.j). No substantial difference can be noticed in the quantitative recurrence of other decoration types such as DWL, Rocker stamp plain and dotted zigzag spaced, and Scraping, while APS decoration appears more rarely (Fig. 3B.q), but always tempered with angular feldspar grains.

Finally, a Middle Mesolithic C phase (6200–6000/5900 BC) is well known from the upper undisturbed layer of the 16-D-3 site at Al Khiday. Pottery sherds are mostly decorated with Rocker stamp fan-like motifs, similar to the Middle Mesolithic B exemplars, and often are red-ochre slipped or in some cases painted. Several

unpatterned Rocker stamp decorations are also attested, as well as more rare DWL, Rocker stamp plain and dotted zigzag spaced, Scraped, and a growing number of APS. IWL is still present but in a reduced number of exemplars. The most interesting pottery type presents a complex decoration made of dotted arches generating a thick vertical pattern of dotted zigzag lines (Fig. 3B.r–s) that can be convincingly compared with the early Laqiya pottery known in the Wadi Howar (Rahib site 80/87, Djabarona 84/13–6 and Conical Hill 84/24), in the Ennedi Erg sites, and in the Sudanese western desert in the Laqiya region (Wadi Shaw: Jesse 2003: 189, Fig. 38). A single fragment possibly of the early Laqiya type was found at El Mahalab in the Wadi Soba (Fernández et al. 2003: Fig. 40: 16). Most of the rims of the Laqiya pottery at Al Khiday are decorated with cord impressions, and the walls are usually covered with a red-ochre slip.

At Shabona (Clark 1989), further to the south, two types of pottery were collected, one grass tempered (Naima ware) that is considered to replace a sand- and feldspar-tempered ware (Shabona ware). Unfortunately the only C14 date (on *Pila* sp. shell: 6028–5798 1σ cal BC) available from the main site cannot be linked to either of the two ware types. The other C14 determination (6566–6071 1σ cal BC) from the site is from a human bone (SH/South/G1). Judging from the limited number of illustrated sherds, the decorative motifs on the Naima grass-tempered ware cannot be compared with the grass-tempered ware from the Southern Dongola Reach and the Multaga area (Karmakol group), and both the groups (Naima and Shabona ware) can only be vaguely assimilated with the Khartoum Horizon.

After a gap in the local sequence, a Late Mesolithic phase (5500–5400 BC) was identified at the site 10-W-4 (Salvatori 2012). Potsherds are mainly decorated with Rocker stamp drops, Rocker stamp dotted zigzag packed (Fig. 3B.t) (as usually feldspar tempered), and Rocker stamp dotted zigzag spaced motifs. IWL is there much less common, as is to be expected considering the trend we observed during the previous Mesolithic phases. APS decoration is well represented and as before it is tempered with crushed feldspar grains. Less frequent are Rocker stamp plain zigzag, incised lines, and Scraped decoration. DWL is present, but it is done in a very compact pattern of a type described as "small waves" by Friederike Jesse (2010: 231).

The sequence described above cannot be applied as such to the entire central Sudan area because, due to the lack of stratigraphy at most if not all of the excavated Mesolithic sites, it is impossible to compare discrete and well-dated pottery assemblages. Contacts were surely actively maintained among hunter-gatherers of the central Sudan, but the decorative system was possibly used as an identity marker and thus indicates the degree of dissimilarity among different groups.

The Neolithic Context

From Foraging to Food Production: The Early and Middle Neolithic of Upper Nubia (Fig. 4)

In the last 25 years, new archaeological excavations and the publication of Neolithic cemeteries and settlements both in Egypt and Sudan have greatly increased our understanding of the neolithization process in northeastern Africa. New data from the Early Neolithic cemetery of El Barga (Honegger 2005) coupled with the data from Tree Shelter and Sodmein Cave (Vermeersch et al. 2015) in the Eastern Egyptian Desert, and from the so-called Middle Neolithic of Nabta Playa and Bir Kiseiba areas in the Egyptian southwestern desert, help to fix a transition from foraging to food production in this core region. Evidence for the introduction of domestic animals (cattle, goat, and sheep) at about 6000 BC comes from the above-quoted sites, while recently analyzed residues from a grave in the R12 cemetery (Ryan et al. 2016), dating to the last centuries of the sixth millennium BC, suggest that together with domestic animals, domestic cereals (wheat and barley) were brought to the area by people coming from southern Levant.

At the Early Neolithic cemetery of El Barga, dated to the first half of the sixth millennium BC, only four vessels have been found in the graves. They are of interest because one is decorated with a Rocker stamp dotted packed pattern of Late

Ceramic Production in the Middle Nile Valley, Sudan (8000 BC–1500 AD), Fig. 4 Selection of diagnostic pottery shapes and decorations from Upper Nubia Middle Neolithic phases (Redrawn from Salvatori and Usai 2008)

Mesolithic tradition that is also present in the almost-contemporary first phase of the Nabta Playa "Middle Neolithic." Among the other vessels found at El Barga, three are a sub-cylindrical undecorated beaker, an open undecorated bowl, and a slightly restricted hemispherical bowl apparently decorated with an uneven herringbone pattern. This limited number of pots from the cemetery cannot help much in understanding local production but gives information on an ongoing process of change from the previous Mesolithic tradition. Early Neolithic grave goods from the El Barga cemetery show the presence of new tools and items of personal decoration in the material assemblage (bone bracelets, small stone axes, necklaces of various kinds of beads, stone lip-plugs, Nile *Chambardia* sp., and red sea shells) that anticipate the more common grave goods present in the fifth millennium BC cemeteries of the Kerma area and the northern Dongola Reach (Reinold 2001; Salvatori and Usai 2008).

Unfortunately, a gap of few centuries ca. 5500 to 5200 BC limits our perception of the evolution of Neolithic societies of Upper Nubia, but, from the end of the sixth and throughout the fifth millennium BC, we can observe pottery production in Upper Nubia through the lens of cemetery data.

The greatest transformation in pottery production is visible during the first half of the fifth

millennium BC (Middle Neolithic A: Fig. 4). Pottery is characterized by a range of vessel shapes, from simple hemispherical unrestricted and restricted bowls to hole-mouth globular and ovoid jars and from biconical composite bowls to a number of caliciform beakers usually found in funerary contexts. Decorative variability is impressive while based on simple technical means (Rocker stamp dotted and plain zigzag, bands of evenly distributed dotted zigzag lines, incised bands hatched with dotted lines). Ripple ware is present in the oldest period of the R12 and the Kadruka 13 cemeteries. This surface treatment is known later at the mid-fifth millennium Gebel Ramlah cemetery, 25 km north of Nabta Playa, and in the so-called Late Neolithic of Nabta at Site E-00-1, as well as, sporadically, in the Abkan Neolithic. Pots are still made by coiling and in some cases possibly thinned using a paddle and anvil technique. Most of the pots from the R12 cemetery are externally and, in cases of open bowls, internally very well smoothed and in many cases polished after decoration. Temper is mostly fine sand, while mica, almost always visible, possibly came from the local Nile clay. More rarely, other materials such as vegetal elements, limestone splinters, and shell fragments were added. Firing was accomplished in earthen kilns to judge from the frequent occurrence of black or red spots produced by an inadequate control of the airflow.

The Middle Neolithic A phase is known in Upper Nubia from the site of Sedeinga to the north, and the Letti Basin and the Fourth Cataract area to the south. Connections with the so-called Abkan Neolithic (Nordström 1972: 12–17) have been highlighted, concerning both pottery and lithic production. As for the oldest period at the R12 cemetery and for the Abkan Neolithic, we now have radiocarbon determinations from Sai Island, pointing to at least the second half of the sixth millennium BC. Abkan pottery is sand tempered, sometimes burnished and decorated with parallel rows of impressed dots in zigzag patterns. Herringbone-incised patterns are also present. While the Abkan is mostly concentrated along the Nile from Faras, north of the Second Cataract, to Sai Island, south of same cataract, connections have been suggested with western desert sites (Wadi Shaw and Wadi Sahal in the Laqiya region). Moreover, it is possible that this culture was present much further to the south, if it can be equated with the so-called Karat group of the southern Dongola Reach.

The lack of systematic publication of contemporary excavated cemeteries in the Kerma area does not allow meaningful tracing of variability in pottery production in the region and thus the identification of specific identity markers for each local community.

At about 4500 BC, a new pottery assemblage (Middle Neolithic B: Fig. 4) appeared and spread all over Upper Nubia from the Kerma area and the northern Dongola Reach (Kadruka 1 and R12 cemeteries) to the Fourth Cataract area (Multaga). This new pottery tradition can denote a period of integration marking the building of a regional identity. This assemblage seems to be limited to a restricted number of shapes, mainly well-polished to burnished subcylindrical jars, slightly flattened small jars, large open bowls with flattened bottoms, unrestricted composite subcylindrical bowls, restricted biconical bowls, and large hemispherical bowls. Decoration is limited to a narrow horizontal band on the exterior of the rim decorated with a Rocker stamp plain zigzag or oblique dotted strokes (Salvatori and Usai 2008: Fig. 13.1b, types 56–64). Caliciform beakers, known in several, apparently local, variants both in Egypt and Sudan and also in the desert areas to the west and east of the Nile (Jesse 2007), are still present in the graves of this period (Salvatori and Usai 2008).

At present only one Neolithic settlement has been excavated in Upper Nubia and published. It was located in the area of the eastern cemetery of Kerma and albeit very eroded a number of aligned postholes where there detected. Radiometric determinations place the site between 4600 and 4300 BC (Honegger 2004: Fig. 1) or within Middle Neolithic B. Indeed, most of the pottery seems to fit the typology of this phase with the addition of some rippled vessel. Suggested connections between the Kerma Neolithic and the A-Group (mainly Classic and Terminal) are at the moment very problematic because of the chronological distance between them.

The Upper Nubian Late Neolithic and the Pre-Kerma (the Fourth Millennium)

At the beginning of the fourth millennium BC at about 3750 BC, an apparently new cultural group (called the A-Group) appeared around the First Cataract and later expanded to the south along the Nile (Nordström 1972). It seems to be present also in the western Nubian desert. The first phase, the Early A-Group (3750–3400 BC), is known at a restricted number of cemeteries around the First Cataract, and the associated materials are mainly of Egyptian origin (Nordström 1972). This phase recently underwent a serious revision and now is understood as part of a Naqada settlement system. The Nubian component can be equated to the Terminal Abkan. Proper Nubian pottery of the period is barely described, but its main component is burnished red-slipped and black-mouthed wares. Less common are incised and impressed geometric patterns on deep bowls.

Black-topped and rippled pottery together with pots decorated with incised and impressed geometric patterns is the most characteristic traits of the Classic or Middle A-Group (ca. 3400–3200 BC). The occurrence of pots with milled rim decoration is noteworthy. A-Group sites and cemeteries are now distributed along the Nile from north of the First Cataract to the Batn el-Hagar south of the Second Cataract. Moreover, sites with A-Group pottery were located in the Wadi Shaw and Wadi Sahal in the Laqiya region (northwestern desert of the Sudan). The local assemblage is made of "rippled sherds, red polished black mouthed sherds and sherds with decorations of zigzag and herring-bone patterns" (Lange 2003: 106, and Figs. 3–5, 7–9).
